The second example of a microporous framework stannosilicate with a known structure (AV-7) has been reported. The structure of AV-7, which is very similar to the structure of both the zirconosilicate mineral kostylevite and the previously reported microporous titanosilicate UND-1, has been studied by the Rietveld method and further characterised by bulk chemical analysis, powder X-ray diffraction, scanning electron microscopy, ²³Na, ²⁹Si and ¹¹⁹Sn magic-angle spinning NMR spectroscopy and thermogravimetry.

Introduction

Recently, the synthesis of inorganic microporous framework solids possessing structures which consist of interconnected octahedral- and tetrahedral-oxide polyhedra has stimulated considerable interest. We have been particularly concerned with the chemistry of microporous titanium and zirconium silicates containing tetracoordinated Si⁴⁺ and Ti⁴⁺ or Zr⁴⁺, usually in octahedral coordination.^{1–4} We have now extended our work to stannosilicates.

Several minerals containing SnO₆ and SiO₄ polyhedra are known and a few (dense) stannosilicate phases have been crystallised from hydrothermal conditions (ref. 5 and references therein). Despite this, very little work is presently available on the synthesis of microporous stannosilicates. Two microporous and a layered stannosilicate have been reported by Corcoran *et al.*⁵ Subsequently, Dyer and Jáfar reported the synthesis of a third microporous stannosilicate.⁶ The structure of all these materials is, however, unknown. The ion-exchange properties of the Dyer and Jáfar stannosilicate have been studied for the replacement of Na⁺ by a range of monovalent and divalent ions.⁷ Thermodynamic parameters have been calculated from isotherm data leading to the conclusion that the exchanges were of zeolite-type character and that the stannosilicate behaves as a microporous solid.

Very recently, we reported the synthesis and structural characterisation of the microporous stannosilicate AV-6 which possesses the structure of mineral umbite.⁸ Here, we report the synthesis of a novel stannosilicate (named AV-7, Aveiro microporous solid no.7) which possesses the structure of both the zirconosilicate mineral kostylevite⁹ and the previously reported titanosilicate known as UND-1.¹⁰

Experimental

AV-7 synthesis

An alkaline solution was made by dissolving sodium metasilicate (12.27 g) (Na₂SiO₃·5H₂O, BDH) and KF (2.45 g) (Aldrich) in H₂O (12.14 g). SnCl₄·5H₂O (3.76 g) (98 m/m%, Riedel-deHaën) was added to the alkaline solution with thorough stirring. This gel, with a molar composition 5.5 Na₂O : 2.0 K₂O : 5.5 SiO₂ : 1.0 SnO₂ : 97 H₂O, was transferred to a Teflon-lined autoclave and treated at 230 °C for 5 days under autogenous pressure without agitation. The crystalline product was filtered off, washed at room temperature with distilled water, and dried at 70 °C overnight, the final product

being an off-white microcrystalline powder. Within experimental error, bulk chemical analysis by ICP suggests for AV-7 the chemical formula Na_{0.5}K_{1.5}SnSi₃O₉·H₂O.

Materials characterisation

Powder X-ray diffraction (XRD) data were collected on a Philipps X'pert MPD diffractometer using Cu-Kα radiation. Rietveld refinement was performed using the program FULL-PROF.¹¹ Table 1 gives the crystallographic data for AV-7. Scanning electron microscope (SEM) images were recorded on a Hitachi S-4100 microscope. ²³Na, ²⁹Si and ¹¹⁹Sn NMR spectra were recorded at 105.85, 79.49 and 149.09 MHz, respectively, on a (9.4 T) Bruker MSL 400 P spectrometer. ²⁹Si MAS NMR spectra were recorded with 40° pulses, a spinning rate of 5.0 kHz and 60 s recycle delays. Chemical shifts are quoted in ppm from TMS. ²³Na MAS NMR spectra were measured using short and powerful radiofrequency pulses (0.6 μs, equivalent to a 15° pulse angle), a spinning rate of 32 kHz and a recycle delay of 2 s. Chemical shifts are quoted in ppm from 1 M aqueous NaCl. ¹¹⁹Sn MAS NMR spectra were recorded with a 40° pulse, a spinning rate of 14 kHz and a recycle delay of 100 s. Chemical shifts are quoted in ppm from Sn(CH₃)₄. Thermogravimetric (TGA) curves were measured with a TGA-50 analyser. The samples were heated under air at a rate of 5 °C min⁻¹.

Results and discussion

SEM (Fig. 1) shows that AV-7 consists of crystals of *ca.* 1.5 × 1.5 × 4.5 μm. The total AV-7 mass loss (ascertained by

TGA) between 30 and 450 °C is *ca.* 4%. This water loss is reversible. Powder XRD shows that the framework of AV-7 is stable up to 450 °C.

The powder XRD pattern of AV-7 could be indexed with DICVOL¹² using a monoclinic unit cell with $a=6.4596$, $b=11.5523$, $c=12.9379\text{ \AA}$, $\beta=104.990^\circ$. Atomic coordinates (space group $P2_1/c$) were derived from those reported for UND-1.¹⁰ The final profile fit is shown in Fig. 2, the atomic coordinates are given in Table 2, and bond distances and bond angles are collected on Tables 3 and 4, respectively.

The structure of AV-7 (Fig. 3) is very similar to the structures of the mineral kostylevite and titanosilicate UND-1¹⁰ and consists of six-membered rings formed by SiO₄ tetrahedra and

isolated SnO₆ octahedra. In order to coordinate the latter, the six-membered rings are tilted with respect to the main channel axis. Each SnO₆ octahedron connects to six SiO₄ tetrahedra on the three six-membered rings of SiO₄ tetrahedra. In this way, three three-membered rings are formed while each SiO₄ tetrahedron connects to both two isolated SnO₆ octahedra and two SiO₆ tetrahedra of the same six-membered ring. In this way, *ca.* 4 Å diameter channels are formed along the [100] direction with eight-membered rings containing –O–Si–O–Sn–O– linkages. The wall of the channel is covered by seven-membered rings (three SnO₆ octahedra and four SiO₄ tetrahedra) which are composed of –Si–O–Si–O– and –Sn–O–Si–O– and by the three-membered rings. There are two

cation sites in the structure of AV-7. One is occupied only by K⁺ and is located near the centre of the seven-membered ring of the wall. In this site K⁺ is coordinated by four framework oxygens from the seven-membered ring and two oxygens from adjacent six-membered rings of SiO₄ tetrahedra. The other cation site has an occupation of 50% K⁺, 50% Na⁺; it is located in the large channel near the wall and is coordinated by six framework oxygens of the wall and two water molecules. Orthorhombic AV-6⁸ and monoclinic AV-7 are two polymorphs of (Na,K)₂SnSi₃O₉·H₂O, just as synthetic zirconous umbite (AM-2)⁴ and kostylevite⁹ are polymorphs of K₂ZrSi₃O₉·H₂O. ²³Na, ²⁹Si and ¹¹⁹Sn solid-state NMR data support the

Fig. 3 Polyhedral representation of the AV-7 structure viewed along [100]. Open and solid circles depict water molecules and (Na,K) cations, respectively.

Fig. 5 Experimental and simulated ^{23}Na MAS NMR spectrum of AV-7.

structure proposed for AV-7. The ^{29}Si MAS NMR spectrum (Fig. 4) displays three overlapping peaks at δ ca. -84.5 , -84.8 and -85.2 with similar intensities. In accord with this observation, the crystal structure of AV-7 calls for the presence of three unique Si (2Si, 2Sn) sites with equal populations. AV-6 also gives three resonances at δ -84.6 , -85.5 and -86.7 .⁸ Other reported framework stannosilicates give resonances in the range δ -78 to -92 .^{5,6}

The ^{119}Sn MAS MNR spectrum of AV-7 (Fig. 4) displays one peak at δ ca. -688 , with a full-width at half-maximum of ca. 1200 Hz, ascribed to the single Sn(6Si) environment present. AV-6 also gives a single peak at δ ca. -709 .⁸ The framework stannosilicates reported by Corcoran and Vaughan which contain octahedral Sn^{IV} give ^{119}Sn MAS MNR signals at δ ca. -706 and -708.3 .⁵

The AV-7 ^{23}Na MAS NMR spectrum (Fig. 5) displays a typical second-order quadrupole powder pattern corresponding to the single cation site occupied by sodium. The simulation of this pattern yields the following parameters: quadrupole coupling constant 1.12 MHz, asymmetry parameter 1.0 and isotropic chemical shift δ -11.4 .

In conclusion, we report the successful synthesis and

structural characterisation of AV-7, a novel framework stannosilicate analogue of mineral kostylevite and titanosilicate UND-1. In view of the interesting ion-exchange properties displayed by a previously reported microporous stannosilicate,⁷ it is worthwhile to explore the possible applications of AV-7 in ion exchange. This work is now in progress in our laboratory.
