Complex $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{P}^i\text{Pr}_3)_2$ (**1**) reacts with equimolecular mixtures of TiPF_6 and alkynes such as phenylacetylene and cyclohexylacetylene to give $[\text{OsH}(\eta^5\text{-C}_5\text{H}_5)(\text{C}\equiv\text{CR})(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ ($\text{R} = \text{Ph}$ (**2**), Cy (**3**)). The structure of **2** in the solid state has been determined by X-ray diffraction analysis. The distribution of ligands around the metallic center can be described as a four-legged piano-stool geometry with the hydride and alkynyl ligands mutually *transoid*. The reaction of **1** with 2-phenyl-3-butyn-2-ol and TiPF_6 leads to $[\text{OsH}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}(\text{OH})\text{MePh}\}(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ (**4**), which evolves into the hydride–enynyl complex $[\text{OsH}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}(\text{Ph})=\text{CH}_2\}(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ (**5**) in solution of chloroform. Treatment of **1** with 1,1-diphenyl-2-propyn-1-ol and TiPF_6 affords $[\text{OsH}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}(\text{OH})\text{Ph}_2\}(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ (**6**), which reacts with KOH in methanol to give the neutral compound $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}(\text{OH})\text{Ph}_2\}(\text{P}^i\text{Pr}_3)_2$ (**7**) by extraction of the hydride ligand. The addition of 1 equiv of HPF_6 to the solutions of **7** leads to the allenylidene, $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ (**8**), which affords the dicationic carbyne derivative $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{CCH}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2](\text{PF}_6)_2$ (**9**) by reaction with HPF_6 . The structure of **9** in the solid state has been also determined by X-ray diffraction analysis. In this case, the geometry around the osmium center is close to octahedral with the triisopropylphosphine ligands mutually *cis* disposed ($\text{P}-\text{Os}-\text{P} = 105.12(8)^\circ$). Complex **8** also reacts with nucleophilic reagents; the reaction with CH_3Li gives $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}(\text{CH}_3)\text{Ph}_2\}(\text{P}^i\text{Pr}_3)_2$ (**10**), whereas the reactions with acetone and methanol solutions of KOH afford $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}[\text{CH}_2\text{C}(\text{O})\text{CH}_3]\text{Ph}_2\}(\text{P}^i\text{Pr}_3)_2$ (**11**) and $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}(\text{OCH}_3)\text{Ph}_2\}(\text{P}^i\text{Pr}_3)_2$ (**12**), respectively. To understand the chemical behavior of **8**, EHT–MO calculations on the model compounds $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CH}_2)(\text{PH}_3)$ (**13**) and $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CH}_2)\text{L}(\text{PH}_3)]^+$ ($\text{L} = \text{PH}_3$ (**14**), CO (**15**)) have been also carried out. The results suggest that the behavior of **8** as nucleophile is a consequence of the high electron density of the allenylidene ligand, while the behavior as γ -electrophile is due to its cationic nature. In addition, we have determined by *ab initio* calculations the energies of stabilization by protonation of **13**–**15** with a naked proton. In the three cases the formation of the corresponding carbyne derivatives $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{CCH}=\text{CH}_2)(\text{PH}_3)]^+$ (**16**; 267 kcal·mol^{−1}), $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{CCH}=\text{CH}_2)(\text{PH}_3)_2]^{2+}$ (**17**; 180 kcal·mol^{−1}), and $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{CCH}=\text{CH}_2)(\text{CO})(\text{PH}_3)]^{2+}$ (**18**; 157 kcal·mol^{−1}) involves a stabilization of the system.

Introduction

Diarylallenylidene complexes of the iron triad have attracted a great deal of attention in recent years as a new type of organometallic intermediate that may have unusual reactivity in stoichiometric¹ and catalytic processes.²

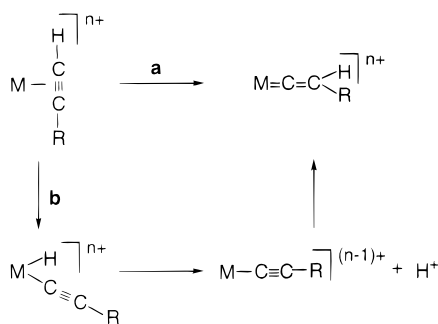

Since the beginning, the dehydration of hydroxyvinylidene has been proposed as the reasonable previous step to allenylidene. This reaction implicates the coordination of the carbon–carbon triple bond of propargyl alcohols $\text{HC}\equiv\text{CC}(\text{OH})\text{R}_2$, followed by tautomerization.³

Scheme 1

The isomerization of the coordinate π -alkynes into vinylidenes has been shown to occur by two alternative pathways (**a** and **b** in Scheme 1), either intramolecular 1,2-hydrogen migration or via hydride–alkynyl species.⁴ Pathway **b** is enhanced by basic metallic fragments, which favor the H–C(sp) activation of the alkyne.⁵ Once the hydride–alkynyl intermediates are formed, the hydride dissociates as a proton, yielding alkynyl species. Protonation of these intermediates at the C_β atom affords the vinylidene derivatives. As a consequence of the common ion effect, the addition of strong acids inhibits the isomerization through pathway **b**.^{5,6}

The reactivity of the C_3 -organic unit of the allenylidene ligand of diarylallenylidene complexes of the iron triad strongly depends on the particular metallic fragment stabilizing the unsaturated ligand. Thus, according to the behaviors reported to the present, the compounds can be classified into three groups.

(i) Nucleophiles. The most representative example of this type is the neutral osmium(II) complex $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)$. The C_3 -organic unit of this compound does not react with water, alcohols, phosphines, amines, or strongly nucleophilic reagents. However, it adds HBF_4 and dimethyl acetylenedicarboxylate to give $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{CCH}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)]\text{BF}_4$ and $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}[\text{C}=\text{C}(\text{CO}_2\text{Me})\text{C}(\text{CO}_2\text{Me})=\text{C}=\text{CPh}_2](\text{P}^i\text{Pr}_3)$, respectively.⁷

(ii) γ -Electrophiles. The diarylallenylidene ligands show this behavior when they are bonded to cationic metallic fragments such as $[\text{RuCl}(\text{dppm})_2]^+$ ($\text{dppm} = \text{Ph}_2\text{PCH}_2\text{PPh}_2$),⁸ $[\text{Ru}(\eta^5\text{-C}_5\text{R}_5)(\text{PR}'_3)_2]^+$ ($\text{R} = \text{H, Me}$),^{3,9}

$[\text{Ru}(\eta^5\text{-C}_9\text{H}_7)\text{L}_2]^+$ ($\text{L}_2 = 2 \text{ PR}_3$, diphosphine),¹⁰ $[\text{RuCl}\{\text{N}-(\text{CH}_2\text{CH}_2\text{PPh}_2)_3\}]^+$,¹¹ or $[\text{Os}\{\text{C}[\text{C}(\text{O})\text{OCH}_3]=\text{CH}_2\}(\text{CO})-(\text{P}^i\text{Pr}_3)_2]^+$.¹² In such cases, the diarylallenylidene moieties do not undergo intermolecular addition of weakly nucleophilic reagents (water, alcohols, amines, etc.), and the reactions with strong nucleophiles such as methoxide, alkyl, and acetylide lead to functionalized alkynyl compounds as a result of the regioselective addition of the reagents at the C_γ atom of the diarylallenylidene group.

(iii) α -Electrophiles. The best known complex of this type is the derivative $[\text{Ru}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{CO})-(\text{P}^i\text{Pr}_3)]^+$.¹³ The reactivity of the C_3 -organic unit of this compound is characterized by its strong trend to add RXH molecules at the $\text{C}_\alpha\text{--C}_\beta$ double bond, to afford cationic complexes of the type $\text{Ru}\{\text{C}(\text{XR})\text{CH}=\text{CPh}_2\}$. The diphenylallenylidene ligand stabilized by the metallic fragments $[\text{Ru}(\eta^5\text{-C}_9\text{H}_4\text{Me}_3)(\text{CO})(\text{PPh}_3)]^+$ ¹⁴ and $[\text{Ru}(\eta^6\text{-C}_6\text{H}_4\text{X}_2)\text{Cl}(\text{PMe}_3)]^+$ ($\text{X} = \text{H, Me}$)¹⁵ shows similar behavior.

As a part of our study on the chemical properties of the six-coordinate osmium(IV) complex $\text{OsH}_2\text{Cl}_2(\text{P}^i\text{Pr}_3)_2$, we have recently reported the synthesis of the half-sandwich derivative $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{P}^i\text{Pr}_3)_2$.¹⁶ Despite the high kinetic stability of the OsCpL_3 compounds,¹⁷ this complex is a labile starting material for the development of new cyclopentadienyl–osmium chemistry.^{7,18} As a continuation of our work in this field, we now show that the complex $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{P}^i\text{Pr}_3)_2$ allows the prepara-

tion of the first hydride–alkynyl derivatives of osmium(IV), and the allenylidene complex [Os(η^5 -C₅H₅)(C=C=CPh₂)(PⁱPr₃)₂]/PF₆, which is of interest not only because the osmium allenylidene compounds are very rare¹⁹ but also because the chemical properties of this new complex are intermediate between those previously mentioned for nucleophilic and γ -electrophilic diarylallenylidene derivatives. In addition, we report the analysis of the electronic structures of the model complexes Os(η^5 -C₅H₅)Cl(C=C=CH₂)(PH₃) and [Os(η^5 -C₅H₅)(C=C=CH₂)L-(PH₃)]⁺ (L = PH₃, CO), to understand why the cation [Os(η^5 -C₅H₅)(C=C=CPh₂)(PⁱPr₃)₂]⁺ has a different behavior from the previously reported allenylidene compounds.

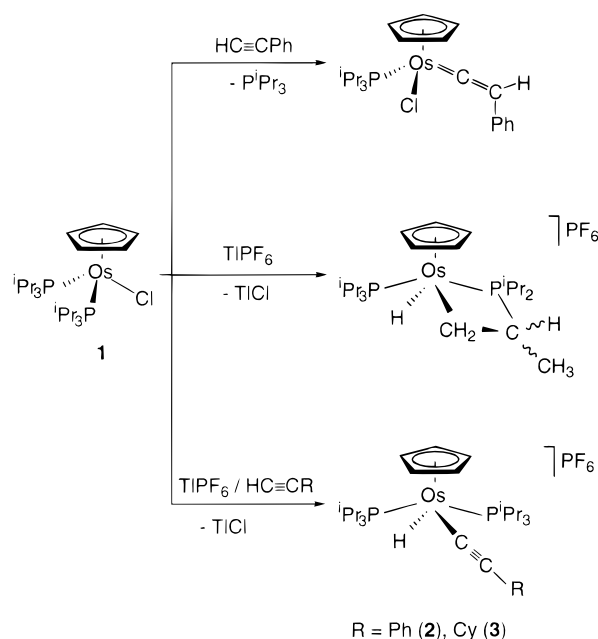

Results and Discussion

1. Synthesis and Characterization of [OsH(η^5 -C₅H₅)(C≡CR)(PⁱPr₃)₂]/PF₆ (R = Ph, Cy). In pentane and toluene, complex Os(η^5 -C₅H₅)Cl(PⁱPr₃)₂ (**1**) reacts with phenylacetylene to give the vinylidene derivative Os(η^5 -C₅H₅)Cl(C=CHPh)(PⁱPr₃) via the π -alkyne intermediate Os(η^5 -C₅H₅)Cl(η^2 -HC≡CPh)(PⁱPr₃). On the other hand, in polar solvents or in the presence of TlPF₆ the splitting of the Os–Cl bond of **1** is favored, and the resulting [Os(η^5 -C₅H₅)(PⁱPr₃)₂]⁺ metallic fragment is capable of activating a methyl C–H bond of a triisopropylphosphine to give [OsH(η^5 -C₅H₅){CH₂CH(CH₃)PⁱPr₂}(PⁱPr₃)]⁺.¹⁶

In contrast to the above-mentioned reactions, the combined treatment of **1** with alkynes, such as phenylacetylene or cyclohexylacetylene, and TlPF₆ in a 1:15 acetone/dichloromethane mixture as solvent leads to the hydride–alkynyl–osmium(IV) complexes [OsH(η^5 -C₅H₅)(C≡CR)(PⁱPr₃)₂]/PF₆ (R = Ph (**2**), Cy (**3**)), as a result of the H–C(sp) oxidative addition of the alkynes to the [Os(η^5 -C₅H₅)(PⁱPr₃)₂]⁺ metallic fragment (Scheme 2). Evidence for the participation of π -alkyne intermediates during the formation process of **2** and **3** was not found.

The ruthenium complex Ru(η^5 -C₅Me₅)Cl(dippe) (dippe = ⁱPr₂PCH₂CH₂PⁱPr₂) reacts with terminal alkynes in the presence of NaBPh₄ to give vinylidene derivatives via hydride–alkynyl–ruthenium(IV) intermediates related to **2** and **3**, whereas, under the same conditions, the formation of the analogous vinylidene complexes containing the [Ru(η^5 -C₅H₅)(dippe)]⁺ unit proceeds through π -alkyne intermediates. To rationalize these observations, it has been argued that the pathways **a** and **b** of Scheme 1 are competitive, and the choice of either **a** or **b** is determined by the electron density of the metallic fragment.⁵ At first glance, the formation of **2** and **3** is in agreement with this. The intrinsically higher basicity of the osmium atom in comparison with ruthenium²¹ could explain why the metallic fragment [Os(η^5 -C₅H₅)(PⁱPr₃)₂]⁺ favors the H–C(sp) oxidative addition, while the [Ru(η^5 -C₅H₅)(dippe)]⁺ unit gives rise to the formation of vinylidene derivatives by intramolecular 1,2-hydrogen shift. However, it should be noted

Scheme 2

that, in the presence of phenylacetylene, the metallic fragment Os(η^5 -C₅H₅)Cl(PⁱPr₃)₂, which reacts with HX (X = H, SiR₃, GeR₃, SnR₃, Cl) molecules to give OsH(η^5 -C₅H₅)XCl(PⁱPr₃)₂,^{18c} shows the same behavior as [Ru(η^5 -C₅H₅)(dippe)]⁺. Furthermore, in contrast to the above-mentioned hydride–alkynyl–ruthenium(IV) species stabilized by the [Ru(η^5 -C₅Me₅)(dippe)]⁺ unit, complexes **2** and **3** do not rearrange to either vinylidene or π -alkyne isomers in the solid state or in solution.

The reasons for the *anomalous* behavior of the metallic fragment [Os(η^5 -C₅H₅)(PⁱPr₃)₂]⁺ may be (i) the electrophilic power of the hydride ligands of **2** and **3** is significantly weaker than that of [RuH(η^5 -C₅Me₅)(C≡CR)(dippe)]⁺, and (ii) the formation of hydride–alkynyl species also takes place by an intermolecular process without previous coordination of the carbon–carbon triple bond of the alkyne.²² The noncoordination of alkynes to [Os(η^5 -C₅H₅)(PⁱPr₃)₂]⁺ could explain why this fragment does not form vinylidene derivatives, while the unit Os(η^5 -C₅H₅)Cl(PⁱPr₃) affords Os(η^5 -C₅H₅)Cl(C=C=HPh)(PⁱPr₃).²³

From an electronic point of view, the fragments [Os(η^5 -C₅H₅)(PⁱPr₃)₂]⁺ and Os(η^5 -C₅H₅)Cl(PⁱPr₃) are not significantly different (vide infra). Thus, the different behavior should be steric in origin. The approach of an alkyne to an Os(η^5 -C₅H₅)L₂ metallic fragment can be parallel to the L–L vector or alternatively perpendicular, and the first approach requires more space around the metallic center than the second one. Furthermore, the parallel approach could give rise to either the coordination of the carbon–carbon triple bond or the H–C(sp) activation, while the perpendicular approach should give rise only to the H–C(sp) activation.

Two triisopropylphosphine groups generate a larger steric hindrance than the chloride and the phosphine

(19) The osmium–allenylidene complexes previously reported are Os(η^5 -C₅H₅)X(C=C=CPh₂)(PⁱPr₃) (X = Cl, I),⁷ [Os{C[C(O)OCH₃]=CH₂}(C=C=CPh₂)(CO)(PⁱPr₃)₂]/BF₆,¹² [Os(η^5 -C₅H₅)(C=C=CPh₂)(PPh₃)₂]/PF₆,^{10b} and [(PPh₃)₂(η^5 -C₅H₅)Os=C=C=CHC≡C–Os(η^5 -C₅H₅)(PPh₃)₂]⁺.²⁰

(22) The intermolecular vinylic oxidative addition has been previously proven. See: Stoutland, P. O.; Bergman, R. G. *J. Am. Chem. Soc.* **1988**, *110*, 5732.

(23) Attempts to obtain **2** and **3** by reaction of [OsH(η^5 -C₅H₅){CH₂CH(CH₃)PⁱPr₂}(PⁱPr₃)]⁺ with the corresponding alkyne were unsuccessful.

Scheme 3

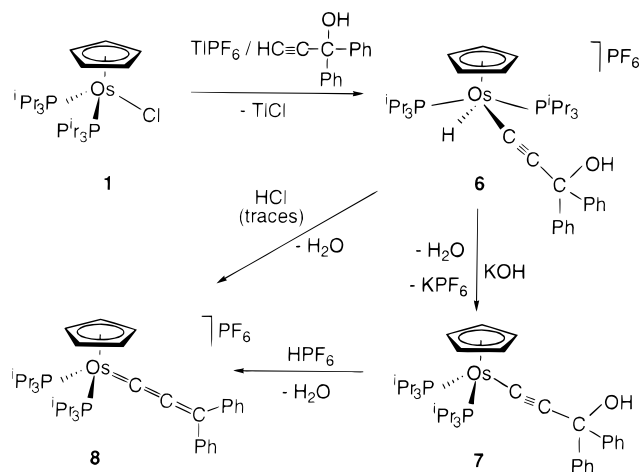

different not only in the presence of phenylacetylene and cyclohexylacetylene but also in the presence of 2-phenyl-3-butyne-2-ol. Thus, at 0 °C the complex Ru(η^5 -C₅Me₅)-Cl(PET₃)₂ reacts with the latter alkynol and NaBPh₄ in methanol to give [RuH(η^5 -C₅Me₅){C≡CC(OH)MePh}-(PET₃)₂][BPh₄]. In contrast to **4**, this compound evolves in the solid state and in solution into the hydroxyvinylidene [Ru(η^5 -C₅Me₅){C=CHC(OH)MePh}-(PET₃)₂][BPh₄], which subsequently affords an isomeric mixture of allenylidene and alkenylvinylidene derivatives. A spontaneous dehydration of the hydroxyalkynyl ligand previous to the isomerization is not observed. The formation of the hydride-enynyl complex [RuH(η^5 -C₅Me₅){C≡CC(Ph)=CH₂}(PET₃)₂][BPh₄] related to **5** requires the passing of a dichloromethane solution of the hydride-hydroxyalkynyl compound through acidic alumina. Similarly to its starting material, and in contrast to **5**, this hydride-enynyl complex spontaneously evolves into the corresponding alkenylvinylidene compound, which affords the thermodynamically more stable allenylidene isomer.^{6b} These differences in behavior are due to the less electrophilic power of the hydride ligands of **4** and **5** in comparison with those of the related compounds containing the [Ru(η^5 -C₅Me₅)(PET₃)₂]⁺ unit.

Complexes **4** and **5** were isolated as white solids in 58% (**4**) and 86% (**5**) yield and characterized by MS, elemental analysis, and IR and ¹H, ¹³C{¹H}, and ³¹P{¹H} NMR spectroscopy.

In agreement with the presence of the hydroxyalkynyl ligand in **4**, the IR spectrum of this compound in Nujol shows bands at 3605 and 2113 cm⁻¹, corresponding to the ν (O-H) and ν (C≡C) vibrations, respectively. In the ¹H NMR spectrum in dichloromethane-*d*₂, the most noticeable resonances of the hydroxyalkynyl ligand are two singlets at 2.16 and 1.74 ppm due to the OH proton

Scheme 4

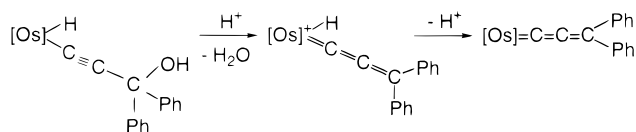

and to the methyl group. In addition, the spectrum contains a double doublet at -13.40 ppm, with H-P coupling constants of 35.7 Hz, which supports the presence of the hydride ligand. In the ¹³C{¹H} NMR spectrum the resonances due to the C_α and C_β atoms of the hydroxyalkynyl ligand appear as double doublets at 48.1 (C_α) and 120.7 (C_β) ppm, with C-P coupling constants of 23.7 (C_α) and 2.5 (C_β) Hz. The ³¹P{¹H} NMR spectrum reveals the asymmetry of the hydroxyalkynyl group, which gives rise to inequivalent phosphines. Thus, the spectrum shows an AB system characterized by the parameters δ_A 7.0, δ_B 6.6, and $J(AB)$ = 23.5 Hz. Under off-resonance conditions a double AB system is observed, as a consequence of the spin-coupling with the hydride ligand.

In the IR spectrum of **5** in Nujol the most noticeable feature is the absence of any ν (O-H) band. The ν (C≡C) and ν (Os-H) vibrations are observed at 2113 and 2035 cm⁻¹, respectively. In the ¹H NMR spectrum in chloroform-*d*, the =CH₂ protons of the enynyl ligand give rise to singlets at 5.38 and 5.00 ppm, whereas the resonance of the hydride ligand appears as a triplet at -13.30 ppm, with an H-P coupling constant of 36.5 Hz. The ¹³C{¹H} NMR spectrum shows three triplets at 133.1, 118.0, and 59.2 ppm, with C-P coupling constants of 2.0, 3.1, and 24.3 Hz, corresponding to the =CPh, C_β, and C_α atoms of the enynyl ligand. The resonance of the =CH₂ atom appears at 117.3 ppm as a singlet. The ³¹P{¹H} NMR spectrum contains a singlet at 6.9 ppm, which under off-resonance conditions is split into a doublet by spin-coupling with the hydride ligand.

3. Synthesis and Characterization of [Os(η^5 -C₅H₅)(C=C=CPh₂)(PⁱPr₃)₂][PF₆]. Treatment, at room temperature, of 1:15 acetone/dichloromethane suspensions of TIPF₆ and 1.52 equiv of 1,1-diphenyl-2-propyn-1-ol with 1 equiv of **1** leads, after 2 min, to the hydride-hydroxyalkynyl-osmium(IV) derivative [OsH(η^5 -C₅H₅){C≡CC(OH)Ph₂}(PⁱPr₃)₂][PF₆] (**6**), as a result of the oxidative addition of the H-C(sp) bond of the alkynol to the unsaturated metallic fragment [Os(η^5 -C₅H₅)-(PⁱPr₃)₂]⁺ (Scheme 4). This compound was isolated as a white solid in 76% yield.

In agreement with the null tendency of this type of systems to isomerize into hydroxyvinylidene derivatives, complex **6** is stable in the solid state and in solution. Even the metallic center can be deprotonated without

Scheme 5

affecting the alkynyl unit. Thus, the addition of 2.7 equiv of KOH to methanol solutions of **6** affords the neutral hydroxyalkynyl compound $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}(\text{OH})\text{Ph}_2\}(\text{P}^i\text{Pr}_3)_2$ (**7**), as a white solid in 73% yield.

Complex **7** reacts with 1 equiv of HPF_6 to give the allenylidene derivative $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]\text{-PF}_6$ (**8**), as a result of the protonation of the $-\text{OH}$ group of the hydroxyalkynyl ligand of **7** (Scheme 4). This complex can be also obtained in a one-pot synthesis by warming of **6** in chloroform under reflux for 6 h. It was isolated as a green solid in 89% yield. Although, it is well-known that the formation of allenylidene complexes starting from hydride–hydroxyalkynyl compounds proceeds via hydroxyvinylidene intermediates,^{1a} the null tendency of **2**, **3**, **4**, and **5** to isomerize into the corresponding hydroxyvinylidene species suggests that in this case the dehydration process is catalyzed by traces of HCl, which are generated from the solvent during the warming process. In agreement with this, the addition of some drops of a HCl toluene solution to **6** in dichloromethane produces the instantaneous formation of **8**.

The formation of **8** can be rationalized according to Scheme 5. The acid could protonate the $-\text{OH}$ group of the hydroxyalkynyl ligand of **6** to give a dicationic hydride–allenylidene intermediate, which should dissociate the protic hydride ligand.

The participation of this intermediate in the formation of **8** agrees well with previous observations.²⁷ The square-planar complexes $\text{OsCl}(\text{NO})(\text{PR}_3)_2$ ($\text{PR}_3 = \text{P}^i\text{Pr}_3$, $\text{P}^i\text{Pr}_2\text{Ph}$) react with 1,1-diphenyl-2-propyn-1-ol to afford the six-coordinate hydride–hydroxyalkynyl–osmium(II) derivatives $\text{OsHCl}\{\text{C}\equiv\text{CC}(\text{OH})\text{Ph}_2\}(\text{NO})(\text{PR}_3)_2$, which similarly to **6** are inert with regard to isomerization to hydroxyvinylidenes. However, they react with chloride-containing acidic alumina to give the η^1 -allenylidene osmium(II) compounds $\text{Os}(\text{CH}=\text{C}=\text{CPh}_2)\text{Cl}_2(\text{NO})(\text{PR}_3)_2$, as a result of the migratory insertion of the hydride ligand into the C_α atom of the allenylidene group of hydride–allenylidene intermediates. The different behavior of these intermediates and that shown in Scheme 5 could be related to the dicationic nature of the latter, which should impose a higher electrophilic character to the hydride ligand hindering its attack at the C_α atom of the allenylidene group. In this context, it should be mentioned that EHT-MO calculations on transition metal allenylidene complexes indicate that the C_α atom of the allenylidene ligand is also an electrophilic center.^{10b,13b,28}

Complexes **6**–**8** were characterized by MS, elemental analysis, and IR and ^1H , $^{13}\text{C}\{^1\text{H}\}$, and $^{31}\text{P}\{^1\text{H}\}$ NMR spectroscopy. The IR spectrum of **6** in Nujol shows the

$\nu(\text{O}-\text{H})$ and the $\nu(\text{C}\equiv\text{C})$ absorptions at 3543 and 2116 cm^{-1} , respectively. In the ^1H NMR spectrum in chloroform-*d*, the most noticeable resonances are a singlet at 2.30 ppm, corresponding to the $-\text{OH}$ proton, and in the high-field region a triplet at -13.40 ppm, which confirms the presence of the hydride ligand. The H–P coupling constant of 35.7 Hz agrees well with those found in **2**–**5** and supports the geometry proposed in Scheme 4. The resonances corresponding to the C_α , C_β , and C_γ atoms of the alkynyl ligand appear in the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum at 53.3, 118.4, and 75.6 ppm, respectively. The first of them is observed as a triplet with a C–P coupling constant of 23 Hz, whereas the others are observed as singlets. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum contains a singlet at 7.2 ppm, which under off-resonance conditions is split into a doublet by spin-coupling with the hydride ligand.

The IR spectrum of **7** in Nujol contains $\nu(\text{O}-\text{H})$ and $\nu(\text{C}\equiv\text{C})$ absorptions at 3532 and 2115 cm^{-1} , respectively. The ^1H NMR spectrum in benzene-*d*₆ shows the $-\text{OH}$ resonance as a singlet at 2.62 ppm. In the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum, the most noticeable features are the chemical shift and the C–P coupling constant of the resonance corresponding to the C_α atom of the hydroxyalkynyl ligand. This resonance is found at 85.9 ppm, shifted 32.6 ppm to lower field in comparison with that of **6**, whereas the C–P coupling constant (17.5 Hz) is 5.5 Hz smaller than that in **6**. The phosphine ligand in the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum gives rise to a singlet at 4.7 ppm.

In agreement with the presence of the allenylidene ligand in **8**, the IR spectrum in Nujol of this compound shows the characteristic $\nu(\text{C}=\text{C}=\text{C})$ band for this type of ligand at 1896 cm^{-1} , and the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum contains a triplet at 255.4 ppm with a C–P coupling constant of 13.8 Hz, which was assigned to the C_α atom, and two singlets at 229.8 and 148.4 ppm, corresponding to the C_β and C_γ atoms, respectively. The chemical shift of the resonance corresponding to the C_α atom and the frequency observed for the $\nu(\text{C}=\text{C}=\text{C})$ band lie between those found for the complexes $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)$ (238.5 ppm and 1874 cm^{-1})⁷ and $[\text{Ru}(\eta^5\text{-C}_5\text{Me}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{PET}_3)_2]^+$ (293.1 ppm and 1907 cm^{-1}).^{6b}

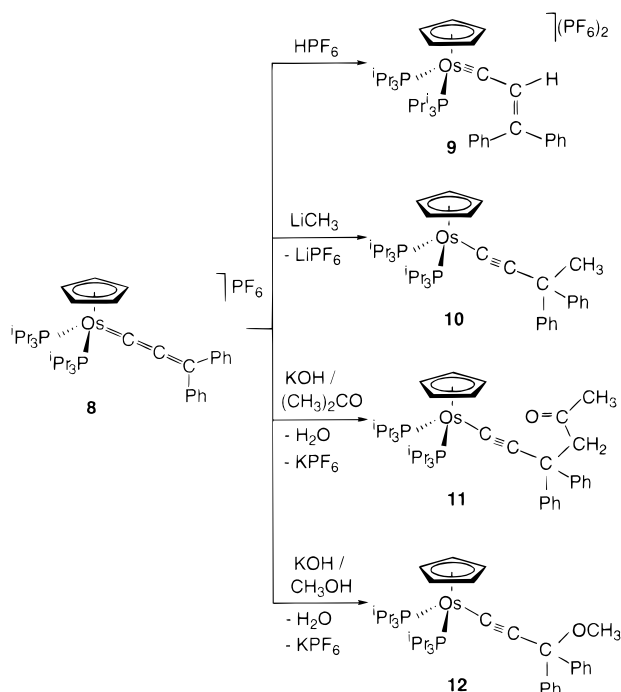

4. Reactivity of $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]\text{-PF}_6$. The investigations aimed at elucidating the reactivity of the allenylidene complex **8** are summarized in Scheme 6. This complex shows not only spectroscopic properties intermediate between the neutral osmium compound $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)$ and the cationic ruthenium derivative $[\text{Ru}(\eta^5\text{-C}_5\text{Me}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{PET}_3)_2]^+$ but also a chemical behavior intermediate between those previously mentioned for the nucleophilic and γ -electrophilic diarylallenylidene complexes. Thus, the C_3 -chain of **8** shows nucleophilic character in the presence of strongly electrophilic reagents and γ -electrophilic character in the presence of strong nucleophiles, while it is inert toward water, alcohols, and amines.

In agreement with the neutral osmium compound $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)$, the C_β atom of the C_3 -chain of **8** adds the proton of HPF_6 . The addition of 1 equiv of this acid to acetone solutions of **8** leads to the dicationic carbyne derivative $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{CCH}=\text{CPh}_2)\text{-}$

Scheme 6

(PⁱPr₃)₂](PF₆)₂ (**9**), which was isolated as a red solid in 86% yield.

The CH= hydrogen atom of the alkenylcarbyne group is relatively acid. When complex **9** is stirred in diethyl ether at room temperature, the C_β atom of the ligand is deprotonated until the equilibrium shown in eq 1 is reached.

In contrast to Os(η^5 -C₅H₅)Cl(C=C=CPh₂)(PⁱPr₃) but in agreement with the γ -electrophilic diarylallenylidene compounds, complex **8** reacts with CH₃Li and acetone and methanol solutions of KOH to give the alkynyl derivatives Os(η^5 -C₅H₅){C≡CC(R)Ph₂}(PⁱPr₃)₂ (R = CH₃ (**10**), CH₂C(O)CH₃ (**11**), OCH₃ (**12**)), as a result of the regioselective addition of the nucleophiles R to the C_γ atom of the allenylidene group. These compounds were isolated as yellow solids in 70–79% yield.

Complex **9** was characterized by MS, elemental analysis, IR and ¹H and ³¹P{¹H} NMR spectroscopy, and an X-ray crystallographic study.²⁹ A view of the molecular geometry of this compound is shown in Figure 2. Selected bond distances and angles are listed in Table 2. The geometry around the osmium center of **9** is close to octahedral, with the cyclopentadienyl ligand occupy-

ing three sites of a face. The P–Os–C(carbyne) angles are close to 90°, while the P–Os–P angle (105.12(8)°) strongly deviates from the ideal value of 90°. This is due to the large steric hindrance experienced by the triisopropylphosphine groups, as a consequence of their large cone angle (160°).³⁰ Transition metal complexes containing bulky phosphine ligands mutually *cis* disposed are rare. P–M–P angles similar to that of **9** have been previously found in the octahedral compounds [Os-

(κ^2 -O₂CCH₃){C(Me)C(OH)Me₂}(PiPr₃)₂]BF₂ (103.71(6)°)

and Os{ η^2 -CH₂=CHC(Ph)₂O}(k²-O₂CCH₃)(PiPr₃)₂ (106.72(4)°),³¹ in the square-planar derivatives Rh(acac)(PCy₃)₂ (105.63(4)°),³² Rh(κ^2 -O₂CCH₃)(PiPr₃)₂ (106.00(4)°),³³ and [Ir(TFB)(PiPr₃)₂]BF₄ (TFB = tetrafluorobenzobarrelene; 102.7(1)°),³⁴ and in the five-coordinate complex [Rh(acac){(*E*)-CH=CHCy}(PCy₃)₂]BF₄ (105.3(1)°).³²

The most conspicuous feature of the structure is the very short Os(1)–C(1) bond length of 1.764(8) Å, which is fully consistent with an Os(1)–C(1) triple bond formulation. Similarly to other carbyne–metal compounds,³⁵ a slight bending in the Os(1)–C(1)–C(2) moiety is also present (Os(1)–C(1)–C(2) = 176.5(7)°).

The alkenylcarbyne proposal is supported by the bond lengths and angles within the η^1 -carbon donor ligand; for example, C(1) and C(2) are separated by 1.410(12) Å and C(2) and C(3) by 1.366(13) Å, and the angles around C(2) and C(3) are in the range 119.9(8)–126.5(9)°.

In agreement with the structure shown in Figure 2, the ^1H NMR spectrum of **9** in acetone- d_6 shows a singlet at 6.66 ppm, corresponding to the =CH proton, and the $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum contains a singlet at 21.6 ppm.

Complexes **10–12** were characterized by MS, elemental analysis, and IR and ^1H , $^{13}\text{C}\{^1\text{H}\}$, and $^{31}\text{P}\{^1\text{H}\}$ NMR spectroscopy. The IR spectrum of **10** in Nujol shows the $\nu(\text{C}\equiv\text{C})$ band at 2080 cm^{-1} . In the ^1H NMR spectrum in benzene- d_6 , the most noticeable resonance is a singlet at 2.06 ppm, corresponding to the methyl group of the alkynyl ligand. The $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum shows the resonance corresponding to the OsC_α atom as a triplet, at 75.9 ppm, with a C–P coupling constant of 6.5 Hz, and that due to the C_β atom of the alkynyl group as a singlet at 108.5 ppm. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum contains a singlet at 4.6 ppm. In agreement with the presence of the functionalized alkynyl ligand of **11**, the IR spectrum of this compound in Nujol shows $\nu(\text{C}\equiv\text{C})$ and $\nu(\text{C}=\text{O})$ bands at 2077 and 1705 cm^{-1} , respectively. In the ^1H NMR spectrum, the presence of the ligand in the complex is supported by two singlets at 3.42 and 1.96 ppm, with a 2:3 intensity ratio, which were assigned to the $-\text{CH}_2-$ and $-\text{CH}_3$ protons. In the $^{13}\text{C}\{^1\text{H}\}$ NMR spectrum, the C_α atom of the alkynyl ligand appears as a triplet at 80.1 ppm with a C–P coupling constant of 7.0 Hz, whereas the C_β atom gives rise to a singlet at 106.7 ppm. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum shows a singlet at 4.6 ppm. In the IR spectrum of **12** in Nujol, the $\nu(\text{C}\equiv\text{C})$ band appears at 2071 cm^{-1} . The ^1H NMR spectrum in chloroform- d shows a singlet at 3.25 ppm, corresponding to the protons of the $-\text{OCH}_3$ group. The

$^{13}\text{C}\{^1\text{H}\}$ NMR spectrum agrees well with those of **10** and **11**, the resonance due to the C_α atom of the alkynyl group is observed as a triplet at 85.9 ppm with a C–P coupling constant of 17.2 Hz, while that corresponding to the C_β atom appears as a singlet at 104.4 ppm. The $^{31}\text{P}\{^1\text{H}\}$ NMR spectrum of **12** shows a singlet at 4.9 ppm.

5. Analysis of the Electronic Structures of $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)$ and $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)\text{L}(\text{P}^i\text{Pr}_3)]^+$ ($\text{L} = \text{P}^i\text{Pr}_3, \text{CO}$). To understand the chemical behavior of **8**, we have carried out the analysis of the electronic structures of $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)$, **8**, and $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{CO})(\text{P}^i\text{Pr}_3)]^+$. Although the carbonyl derivative has not been isolated until now, the behavior of the unit $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{CO})(\text{P}^i\text{Pr}_3)]^+$, in the presence of terminal alkynes and alkynols,^{18a} is similar to the behavior of the metallic fragments which give rise to γ -electrophilic diarylallenylidene compounds. So, we assume that complex $\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{CO})(\text{P}^i\text{Pr}_3)]^+$ would be a new example of γ -electrophilic diarylallenylidene derivative. The study has been performed using EHT-MO calculations³⁶ on the model compounds $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CH}_2)(\text{PH}_3)$ (**13**), $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CH}_2)(\text{PH}_3)_2]^+$ (**14**), and $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CH}_2)(\text{CO})(\text{PH}_3)]^+$ (**15**), and the results are collected in Table 3.

The orbital scheme of the compounds is related to the interaction of the electronic structures of the corresponding metallic fragments and that of the allenylidene ligand, which are well known.³⁷ In agreement with previous studies of this type,^{10b,13b,28} the allenylidene ligand coordinates to the metal centers as a σ -donor and π -acceptor ligand. The σ -donor component of the bonds, which takes place between the HOMO of the allenylidene and the LUMO orbitals of the metallic fragments, produces charge transfers of about 0.4 e from

(35) Schubert, U. Solid-state Structures of Carbyne Complexes. In *Carbyne Complexes*; Fischer, H., Hofmann, P., Kreissl, F. R., Schrock, R. R., Schubert, U., Weiss, K., Eds.; VCH Verlagsgesellschaft mbH: Weinheim, Germany, 1988; p 53.

(36) Mealli, C.; Proserpio, D. M. *J. Chem. Educ.* **1990**, *67*, 399.

(37) Albright, T. A.; Burdett, J. K.; Whangbo, M. H. *Orbital Interactions in Chemistry*; Wiley: New York, 1985.

the ligand to the metallic fragments, whereas the interactions between the HOMO orbitals of the metallic fragments and the LUMO of the allenylidene—the π -acceptor component of the metal–allenylidene bonds—lead to charge transfers from the metallic fragments to the organic ligand of 0.91 (**13**), 0.87 (**14**), and 0.76 (**15**) e. So, from the point of view of the charge, the π -acceptor component of the bonds is stronger than the σ -donor one. The resulting bonds, including all contributions, produce total transfers from the metallic fragments to the allenylidene of 0.44 (**13**), 0.41 (**14**), and 0.26 (**15**) e.

The Mulliken population analysis in the three cases indicates that about 60% of the LUMO of the complexes is located on the allenylidene ligand, mainly on the C $_{\alpha}$ and C $_{\gamma}$ atoms, whereas about 25% of the HOMO is located on the C $_{\beta}$ atom. Furthermore, the net charge on C $_{\alpha}$ atoms is significantly higher than those on the C $_{\beta}$ and C $_{\gamma}$ atoms.

According to the results collected in Table 3, the charge transferred from the metallic fragment [Os(η^5 -C₅H₅)(PH₃)₂]⁺ to the allenylidene ligand is intermediate between those transferred by the metallic fragments of **13** and **15**. This agrees well with the chemical behavior of **8**, which is also intermediate between those of the nucleophilic and γ -electrophilic diarylallenylidene compounds.

In addition, it should be noted that the value of the total charge transfer for **14** is about 7% smaller than that for **13** and about 57% higher than that for **15**. This agrees well with the formation of **9** by protonation of **8** and suggests that the behavior of **8** as γ -electrophile is mainly due to its cationic nature.

The alkenyl group of **9** can be deprotonated by diethyl ether (eq 1). However, under the same conditions, the related compound [Os(η^5 -C₅H₅)Cl(CCH=CPh₂)(PⁱPr₃)₂]⁺ is stable. To explain this difference, we have carried out ab initio calculations³⁸ on the model complexes **13**, **14**, [Os(η^5 -C₅H₅)Cl(CCH=CH₂)(PH₃)₂]⁺ (**16**), and [Os(η^5 -C₅H₅)(CCH=CH₂)(PH₃)₂]²⁺ (**17**). For comparative purpose, calculations on **15** and [Os(η^5 -C₅H₅)(CCH=CH₂)(CO)(PH₃)₂]²⁺ (**18**) were also performed. Figure 3 shows the optimized structures at the MP2 level of the six model species.

The structure of the carbyne compounds **16**–**18** are similar. The structural parameters within the OsCCH=CH₂ unit of **17** are in excellent agreement with those obtained by X-ray diffraction analysis for the related OsCCH=CPh₂ unit of **9**. The main difference between the structures of **17** and **9** is the P–Os–P angle. The calculated value (94.9°) is significantly lower than that obtained from the X-ray diffraction analysis (105.12(8)°). This indicates that, in fact, the deviation observed from the ideal value of 90° in **9** is mainly due to the large

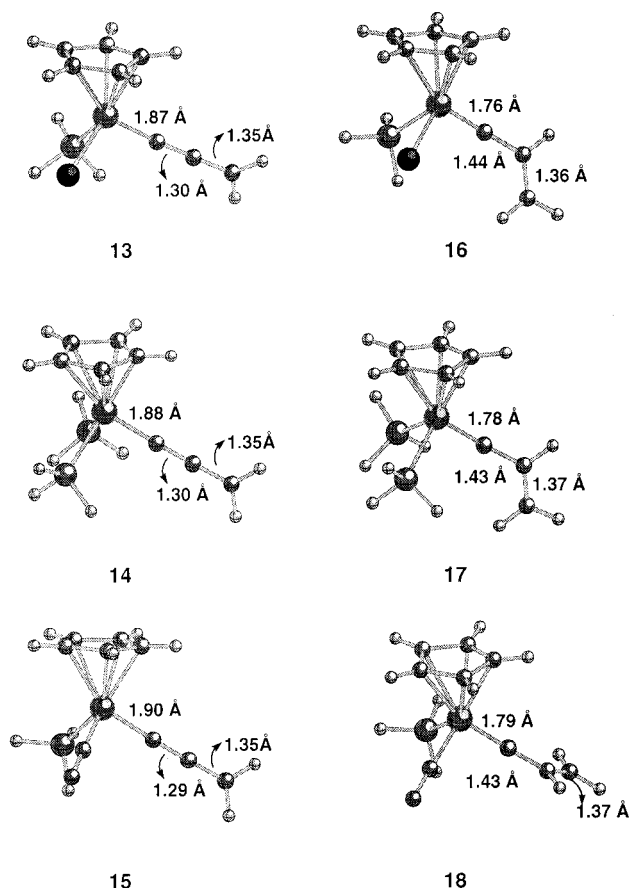

Figure 3. Optimized structures of Os(η^5 -C₅H₅)Cl(C=C=CH₂)(PH₃) (**13**), [Os(η^5 -C₅H₅)(C=C=CH₂)L(PH₃)₂]⁺ (L = PH₃ (**14**), CO (**15**)), [Os(η^5 -C₅H₅)Cl(CCH=CH₂)(PH₃)₂]⁺ (**16**), and [Os(η^5 -C₅H₅)(CCH=CH₂)L(PH₃)₂]²⁺ (L = PH₃ (**17**), CO (**18**)).

steric hindrance experienced by the triisopropylphosphine groups.

The structures of the allenylidene complexes **13**–**15** are also similar, and the structural parameters of the OsC=C=CPh₂ unit of **13** are in excellent agreement with those obtained by X-ray diffraction analysis for the related OsC=C=CPh₂ unit of Os(η^5 -C₅H₅)Cl(C=C=CPh₂)(PⁱPr₃)₂.⁷

For the three metallic fragments, Os(η^5 -C₅H₅)Cl(PH₃), [Os(η^5 -C₅H₅)(PH₃)₂]⁺, and [Os(η^5 -C₅H₅)(CO)(PH₃)₂]⁺, the addition of a naked proton at the allenylidene to give the corresponding carbyne derivatives produces a stabilization of the system. The energy of stabilization by protonation is 267 kcal·mol^{−1} for Os(η^5 -C₅H₅)Cl(PH₃), 180 kcal·mol^{−1} for [Os(η^5 -C₅H₅)(PH₃)₂]⁺, and 157 kcal·mol^{−1} for [Os(η^5 -C₅H₅)(CO)(PH₃)₂]⁺. The difference between the energy of stabilization by protonation obtained for the neutral compound **13** and the cationic complex **14** (87 kcal·mol^{−1}) can explain why complex **9** is deprotonated by diethyl ether, while the carbyne [Os(η^5 -C₅H₅)Cl(CCH=CPh₂)(PⁱPr₃)₂]⁺ is inert under the same conditions.

The energy of stabilization by protonation obtained for **15** is 23 kcal·mol^{−1} lower than that for **14**. This, together with the fact that complex **9** is unstable in the presence of very weak bases, can also explain why the γ -electrophilic diarylallenylidene complexes do not react with acids to form carbyne derivatives, under the usual experimental conditions.

Concluding Remarks

This study has revealed that the combined treatment of the complex $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{P}^i\text{Pr}_3)_2$ with alkynes, such as phenylacetylene, cyclohexylacetylene, 2-phenyl-3-butyn-2-ol, or 1,1-diphenyl-2-propyn-1-ol and TiPF_6 leads to $[\text{OsH}(\eta^5\text{-C}_5\text{H}_5)(\text{C}\equiv\text{CR})(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$, as a result of the intermolecular H–C(sp) oxidative addition of the alkynes to the metallic fragment $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{P}^i\text{Pr}_3)_2]^+$. These complexes are the first examples of hydride–alkynyl–osmium(IV) derivatives and, in contrast to related hydride–alkynyl–ruthenium(IV) compounds, do not rearrange to either vinylidene or π -alkyne isomers in the solid state or in solution.

Complex $[\text{OsH}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}\equiv\text{CC}(\text{OH})\text{Ph}_2\}(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ evolves into the allenylidene derivative $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)\{\text{C}=\text{C}=\text{CPh}_2\}(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ in the presence of traces of acid. The reactivity of this allenylidene is a new case in the chemistry of the diaryllallenylidene complexes of the iron triad. The behavior of the unsaturated C_3 -chain of this ligand is intermediate between those observed for nucleophilic and γ -electrophilic diaryllallenylidene derivatives.

In agreement with the nucleophilic diaryllallenylidene compounds, complex $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ reacts with HPF_6 to give $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{CCH}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2](\text{PF}_6)_2$. However, in contrast to nucleophilic diaryllallenylidene compounds, but in agreement with the γ -electrophiles, it undergoes the regioselective addition of nucleophilic reagents at the C_γ atom of the allenylidene to give functionalized-alkynyl derivatives.

EHT-MO calculations indicate that the electron density on the C_3 -chain of the allenylidene ligand of $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]^+$ is similar to that on the C_3 -chain of the diaryllallenylidene ligands of the nucleophilic complexes of this type, while it is significantly higher than that on the allenylidene ligands of the γ -electrophiles. This suggests that the behavior of $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]^+$ as nucleophile is a consequence of the high electron density of its allenylidene ligand, while the behavior as γ -electrophile is due to the cationic nature of the complex.

Although complex $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]^+$ is protonated like the nucleophilic diaryllallenylidene compounds, ab initio calculations on the model species $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CH}_2)(\text{PH}_3)$, $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CH}_2)(\text{PH}_3)_2]^+$, $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{CCH}=\text{CH}_2)(\text{PH}_3)]^+$, and $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{CCH}=\text{CH}_2)(\text{PH}_3)_2]^{2+}$ indicate that energy of stabilization by protonation with a naked proton of $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{C}=\text{C}=\text{CH}_2)(\text{PH}_3)$ is 87 kcal·mol^{−1} higher than that corresponding to the protonation of $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CH}_2)(\text{PH}_3)_2]^+$. This agrees well with experimental observations showing that the =CH hydrogen atom of the carbyne ligand of $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{CCH}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]^{2+}$ is fairly acidic and can be deprotonated by weak bases such as diethyl ether, while the complex $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{CCH}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)]^+$ is stable under the same conditions.

In conclusion, the unit $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{P}^i\text{Pr}_3)_2]^+$ is a useful metallic fragment to stabilize novel hydride–alkynyl, allenylidene, and carbyne compounds, which have a chemical behavior different from those observed for the previously reported compounds of the iron triad containing these functional groups. In particular, the complex $[\text{Os}(\eta^5\text{-C}_5\text{H}_5)(\text{C}=\text{C}=\text{CPh}_2)(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ should be

mentioned, which shows an amphoteric behavior between nucleophile and γ -electrophile and, from the reactivity point of view, is the first example of a new class of diaryllallenylidene derivative within the iron triad.

Experimental Section

All reactions were carried out with exclusion of air using standard Schlenk techniques. Solvents were dried by known procedures and distilled under argon prior to use. The complex $\text{Os}(\eta^5\text{-C}_5\text{H}_5)\text{Cl}(\text{P}^i\text{Pr}_3)_2$ (**1**) was prepared according to the literature method.¹⁶

In the NMR spectra, chemical shifts are expressed in ppm downfield from Me_4Si (¹H and ¹³C) and 85% H_3PO_4 (³¹P).

Preparation of $[\text{OsH}(\eta^5\text{-C}_5\text{H}_5)(\text{C}\equiv\text{CPh})(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ (2**).** A suspension of TiPF_6 (79 mg, 0.23 mmol) in 1 mL of acetone was treated with a solution of phenylacetylene (38 μL , 0.35 mmol) in 15 mL of dichloromethane. After the mixture was stirred for 10 min at room temperature, in the absence of light, it was treated with **1** (138 mg, 0.23 mmol). The resulting suspension was stirred for 2 min at room temperature and filtered through Kieselguhr. The solvent was removed in vacuo, and addition of diethyl ether to the residue afforded a white solid, which was washed twice with 5 mL of diethyl ether and twice with 5 mL of a mixture of diethyl ether/methanol (2:1). Yield: 115 mg, 61%. IR (Nujol): $\nu(\text{C}\equiv\text{C})$ 2112, $\nu(\text{PF}_6)$ 840 cm^{−1}. ¹H NMR (300 MHz, CDCl_3 , 293 K): δ 7.20–7.03 (m, 5 H, Ph), 5.75 (s, 5 H, Cp), 2.55 (m, 6 H, PCH), 1.38 (dvt, 18 H, $J(\text{HH}) = 7.1$ Hz, $N = 14.4$ Hz, PCMe), 1.34 (dvt, 18 H, $J(\text{HH}) = 7.1$ Hz, $N = 13.8$ Hz, PCMe), −13.21 (t, 1 H, $J(\text{PH}) = 35.7$ Hz, OsH). ³¹P{¹H} NMR (121.42 MHz, CDCl_3 , 293 K): δ 6.7 (s, d under off-resonance conditions), −144.8 (sept, $J(\text{PF}) = 714$ Hz, PF_6). ¹³C{¹H} NMR (75.42 MHz, CDCl_3 , 293 K, plus DEPT): δ 130.8 (s, Ph), 128.4 (s, Ph), 126.6 (t, $J(\text{PC}) = 2.1$ Hz, *ipso*-Ph), 126.4 (s, Ph), 118.0 (t, $J(\text{PC}) = 2.5$ Hz, $\equiv\text{CPh}$), 85.9 (s, Cp), 57.2 (t, $J(\text{PC}) = 24.7$ Hz, $\text{OsC}\equiv$), 29.8 (second-order system, PCH), 20.4, 20.3 (both s, PCMe). Anal. Calcd for $\text{C}_{31}\text{H}_{53}\text{F}_6\text{OsP}_3$ (%): C, 45.25; H, 6.49. Found: C, 44.99; H, 6.13. MS (FAB⁺): *m/e* 679 (M^+).

Preparation of $[\text{OsH}(\eta^5\text{-C}_5\text{H}_5)(\text{C}\equiv\text{CCy})(\text{P}^i\text{Pr}_3)_2]\text{PF}_6$ (3**).** A suspension of TiPF_6 (141 mg, 0.40 mmol) in 1 mL of acetone was treated with a solution of cyclohexylacetylene (100 μL , 0.76 mmol) in 15 mL of dichloromethane. After the mixture was stirred for 10 min at room temperature, in the absence of light, it was treated with **1** (244 mg, 0.40 mmol). The resulting suspension was stirred for 2 min at room temperature and concentrated to dryness. The residue was extracted with 10 mL of dichloromethane, the suspension was filtered through Kieselguhr, and the solution was concentrated to dryness. The white solid obtained was washed twice with 3 mL of a mixture of diethyl ether/methanol (5:1). Yield: 171.6 mg, 53%. IR (Nujol): $\nu(\text{C}\equiv\text{C})$ 2108, $\nu(\text{PF}_6)$ 840 cm^{−1}. ¹H NMR (300 MHz, CD_2Cl_2 , 293 K): δ 5.63 (s, 5 H, Cp), 2.54 (m, 6 H, PCH), 1.71 (br, 2 H, Cy), 1.64 (br, 2 H, Cy), 1.52 (br, 2 H, Cy), 1.36–1.18 (m, 41 H, PCMe and Cy), −13.50 (t, 1 H, $J(\text{PH}) = 36.3$ Hz, OsH). ³¹P{¹H} NMR (121.42 MHz, CD_2Cl_2 , 293 K): δ 5.6 (s, d under off-resonance conditions), −144.8 (sept, $J(\text{PF}) = 714$ Hz, PF_6). ¹³C{¹H} NMR (75.42 MHz, CDCl_3 , 293 K): δ 121.4 (t, $J(\text{PC}) = 2.5$ Hz, $\equiv\text{CCy}$), 85.5 (s, Cp), 36.4 (t, $J(\text{PC}) = 24.9$ Hz, $\text{OsC}\equiv$), 33.9, 32.3 (both s, Cy), 29.7 (second-order system, PCH), 25.8, 25.4 (both s, Cy), 20.4, 20.3 (both s, PCMe). Preparation of [OsH(η^5 -C₅H₅){C \equiv CC(OH)Ph₂}(PⁱPr₃)₂]-PF₆ (6). A suspension of TIPF₆ (88 mg, 0.25 mmol) in 1 mL of acetone was treated with a solution of 1,1-diphenyl-2-propyn-1-ol (79 mg, 0.38 mmol) in 15 mL of dichloromethane. After the mixture was stirred for 10 min at room temperature, in the absence of light, it was treated with **1** (150 mg, 0.25 mmol). The resulting suspension was stirred for 2 min at room temperature and filtered through Kieselguhr. The solvent was removed in vacuo, and addition of diethyl ether to the residue afforded a white solid, which was washed twice with 3 mL of diethyl ether and twice with 3 mL of a mixture of diethyl ether/methanol (4:1) to afford a white solid. Yield: 170 mg, 76%. IR (Nujol): $\nu(\text{OH})$ 3543, $\nu(\text{C}\equiv\text{C})$ 2116, $\nu(\text{PF}_6)$ 840 cm⁻¹. ¹H NMR (300 MHz, CDCl₃, 293 K): δ 7.39–7.18 (m, 10 H, Ph), 5.73 (s, 5 H, Cp), 2.36 (m, 6 H, PCH), 2.30 (s, 1 H, OH), 1.18 (dvt, 18 H, $J(\text{HH})$ = 6.9 Hz, N = 13.8 Hz, PCMe), 1.13 (dvt, 18 H, $J(\text{HH})$ = 6.9 Hz, N = 14.4 Hz, PCMe), -13.40 (t, 1 H, $J(\text{PH})$ = 35.7 Hz, OsH). ³¹P{¹H} NMR (121.42 MHz, CDCl₃, 293 K): δ 7.2 (s, d under off-resonance conditions), -144.8 (sept, $J(\text{PF})$ = 714 Hz, PF₆). ¹³C{¹H} NMR (75.42 MHz, C₆D₆, 293 K): δ 147.0 (s, *ipso*-Ph), 128.5, 127.9, 126.8 (all s, Ph), 118.4 (s, $\equiv\text{CC}$), 85.9 (s, Cp), 75.6 (s, COH), 53.3 (t, $J(\text{PC})$ = 23 Hz, OsC \equiv), 30.2 (second-order system, PCH), 20.6 (s, PCMe). Anal. Calcd for C₃₈H₅₉F₆OOSp₃ (%): C, 49.15; H, 6.40. Found: C, 48.89; H, 6.15. MS (FAB⁺): *m/e* 785 (M⁺).

Preparation of Os(η^5 -C₅H₅){C \equiv CC(OH)Ph₂}(PⁱPr₃)₂ (7). A solution of **6** (115 mg, 0.12 mmol) in 15 mL of methanol was treated with an excess of KOH (18 mg, 0.32 mmol). After the mixture was stirred for 30 min at room temperature, the resultant solution was evaporated to dryness. The residue was extracted with 10 mL of toluene, and the mixture was filtered

through Kieselguhr. The solution was concentrated to dryness, and the white solid obtained was washed with 1 mL of pentane and dried in vacuo. Yield: 81 mg, 73%. IR (Nujol): $\nu(\text{OH})$ 3532, $\nu(\text{C}\equiv\text{C})$ 2115 cm⁻¹. ¹H NMR (300 MHz, C₆D₆, 293 K): δ 8.00 (m, 4 H, *o*-Ph), 7.25–7.10 (m, 6 H, *p*- and *m*-Ph), 4.75 (s, 5 H, Cp), 2.62 (s, 1 H, OH), 2.18 (m, 6 H, PCH), 1.05 (m, 36 H, PCMe). ³¹P{¹H} NMR (121.42 MHz, C₆D₆, 293 K): δ 4.7 (s). ¹³C{¹H} NMR (75.42 MHz, C₆D₆, 293 K): δ 150.3 (s, *ipso*-Ph), 127.6, 127.5, 126.2 (all s, Ph), 108.7 (s, $\equiv\text{CC}$), 85.9 (t, $J(\text{PC})$ = 17.5 Hz, OsC \equiv), 76.0 (s, COH), 74.9 (t, $J(\text{PC})$ = 1.2 Hz, Cp), 30.5 (second-order system, PCH), 21.2, 20.6 (both s, PCMe). Anal. Calcd for C₃₈H₅₈ClOOSp₂ (%): C, 49.2; H, 6.30. Found: C, 48.96; H, 6.18.

Preparation of [Os(η^5 -C₅H₅)(C=C=CPh₂)(PⁱPr₃)₂][PF₆] (8). A solution of **6** (120 mg, 0.13 mmol) in 15 mL of chloroform was heated at reflux temperature for 6 h. The solvent was removed in vacuo, and the residue was washed twice with 3 mL of diethyl ether to afford a green solid. Yield: 105 mg, 89%. IR (Nujol): $\nu(\text{C}\equiv\text{C})$ 1896, $\nu(\text{PF}_6)$ 840 cm⁻¹. ¹H NMR (300 MHz, CDCl₃, 293 K): δ 7.66–7.28 (m, 10 H, Ph), 5.78 (s, 5 H, Cp), 2.31 (m, 6 H, PCH), 1.15 (dd, 18 H, $J(\text{HH})$ = 6.9 Hz, $J(\text{PH})$ = 13.5 Hz, PCMe), 1.04 (dd, 18 H, $J(\text{HH})$ = 7.2 Hz, $J(\text{PH})$ = 13.8 Hz, PCMe). ³¹P{¹H} NMR (121.42 MHz, CDCl₃, 293 K): δ 7.2 (s), -144.8 (sept, $J(\text{PF})$ = 714 Hz, PF₆). ¹³C{¹H} NMR (75.42 MHz, CDCl₃, 293 K): δ 255.4 (t, $J(\text{PC})$ = 13.8 Hz, Os=C), 229.8 (s, =C=), 149.7 (s, *ipso*-Ph), 148.4 (s, =CPh₂), 129.9, 139.4, 127.8 (all s, Ph), 86.1 (s, Cp), 31.1 (second-order system, PCH), 20.5, 20.3 (both s, PCMe). Anal. Calcd for C₃₈H₅₇F₆Osp₃ (%): C, 50.12; H, 6.31. Found: C, 50.24; H, 6.29.

Reaction of Os(η^5 -C₅H₅){C \equiv CC(OH)Ph₂}(PⁱPr₃)₂ with HPF₆. A solution of **7** (8.2 mg, 0.01 mmol) in 0.5 mL of CDCl₃ was treated, in a NMR tube at room temperature, with HPF₆ (1.2 μ L, 75% in water, 0.01 mmol). The color changed from colorless to green. ¹H and ³¹P{¹H} NMR spectra recorded after 10 min showed quantitative formation of **8**.

Reaction of [OsH(η^5 -C₅H₅){C \equiv CC(OH)Ph₂}(PⁱPr₃)₂][PF₆] with HCl. A solution of **6** (12 mg, 0.01 mmol) in 0.5 mL of CD₂Cl₂ was treated, in a NMR tube at room temperature, with HCl (7 μ L, 0.14 M in toluene, 0.001 mmol). The color changed from colorless to green. ¹H and ³¹P{¹H} NMR spectra recorded after 10 min showed quantitative formation of **8**.

Preparation of [Os(η^5 -C₅H₅){CCH=CPh₂}(PⁱPr₃)₂](PF₆)₂ (9). A solution of **8** (10 mg, 0.01 mmol) in 0.5 mL of acetone-*d*₆ in an NMR tube was treated with HPF₆ (1.2 μ L, 75% in water, 0.01 mmol), and immediately the color turned from green to red. After 5 min at room temperature, the NMR spectra showed only the presence of the compound [Os(η^5 -C₅H₅)(CCH=CPh₂)(PⁱPr₃)₂](PF₆)₂. The red solution was then transferred to a Schlenk tube, and the solvent was partially evaporated until a red solid began to precipitate, which was washed twice with 1 mL of cold acetone. Yield: 10 mg (86%). IR (Nujol): $\nu(\text{PF}_6)$ 840 cm⁻¹. ¹H NMR (300 MHz, (CD₃)₂CO, 293 K): 7.85–7.43 (m, 10 H, Ph), 6.66 (s, 1 H, CH), 6.38 (s, 5 H, Cp), 2.94 (m, 6 H, PCH), 1.49 (dd, $J(\text{HH})$ = 7.2 Hz, $J(\text{PH})$ = 15.9 Hz, 18 H, PCMe), 1.41 (dd, $J(\text{HH})$ = 6.9 Hz, $J(\text{PH})$ = 15.3 Hz, PCMe). ³¹P{¹H} NMR (121.42 MHz, (CD₃)₂CO, 293 K): δ 21.6 (s), -144.8 (sept, $J(\text{PF})$ = 714 Hz, PF₆). Anal. Calcd for C₃₈H₅₈F₁₂Osp₄ (%): C, 43.18; H, 5.53. Found: C, 42.82; H, 5.40. MS (FAB⁺): *m/e* 767 (M⁺ - H).

Preparation of Os(η^5 -C₅H₅){C \equiv CC(CH₃)Ph₂}(PⁱPr₃)₂ (10). A solution of **8** (100 mg, 0.11 mmol) in 7 mL of tetrahydrofuran at -78 °C was treated with methyllithium (69 μ L, 1.6 M in diethyl ether, 0.11 mmol). The mixture was stirred for 1 h while the temperature was increased to room temperature. The solvent was removed in vacuo, the residue was extracted with 7 mL of toluene, and the mixture was filtered through Kieselguhr. The solution was concentrated to dryness, and the residue was washed three times with 2 mL of cold methanol to give a yellow solid. Yield: 60 mg (70%). IR (Nujol): $\nu(\text{C}\equiv\text{C})$ 2080 cm⁻¹. ¹H NMR (300 MHz, C₆D₆, 293 K): 7.74–7.08 (m, 10 H, Ph), 4.81 (s, 5 H, Cp), 2.24 (m, 6 H,

PCH), 2.06 (s, 3 H, CH₃), 1.09 (dvt, $J(\text{HH}) = 7.2$ Hz, $N = 11.1$ Hz, 36 H, PCMe). $^{31}\text{P}\{^1\text{H}\}$ NMR (121.42 MHz, C₆D₆, 293 K): δ 4.6 (s). $^{13}\text{C}\{^1\text{H}\}$ NMR (75.42 MHz, CD₂Cl₂, 293 K): δ 152.0 (s, *ipso*-Ph), 128.0, 127.6, 125.2 (all s, Ph), 108.5 (s, $\equiv\text{CC}$), 75.9 (t, $J(\text{PC}) = 6.5$ Hz, OsC \equiv), 74.7 (s, Cp), 47.2 (s, CPh₂), 31.9 (s, CH₃), 30.9 (second-order system, PCH), 21.6 (s, PCMe), 20.9 (s, PCMe). Anal. Calcd for C₃₉H₆₀OsP₂ (%): C, 59.97; H, 7.74. Found: C, 59.70; H, 7.84. MS (FAB⁺): m/e 783.5 ($\text{M}^+ + \text{H}$).

Preparation of Os(η^5 -C₅H₅){C \equiv CC[CH₂C(O)CH₃]Ph₂}-(P^iPr_3)₂ (11). A solution of **8** (60 mg, 0.07 mmol) in 8 mL of tetrahydrofuran was treated with a suspension of KOH (50 mg, 85%, 0.76 mmol) in 0.5 mL of acetone, and the mixture was stirred for 1 h at room temperature. The resulting yellow solution was concentrated to dryness, the residue was extracted with 7 mL of toluene, and the mixture was filtered through Kieselguhr. The solvent was removed in vacuo, and the residue was washed three times with 2 mL of methanol to give a yellow solid. Yield: 43 mg (79%). IR (Nujol): $\nu(\text{C}\equiv\text{C})$ 2077, $\nu(\text{C}=\text{O})$ 1705 cm⁻¹. ^1H NMR (300 MHz, C₆D₆, 293 K): 7.40–7.09 (m, 10 H, Ph), 4.82 (s, 5 H, Cp), 3.42 (s, 2 H, CH₂), 2.25 (m, PCH), 1.96 (s, 3 H, CH₃), 1.12 (dvt, 36 H, $J(\text{HH}) = 10.5$ Hz, $N = 17.4$ Hz, PCMe). $^{31}\text{P}\{^1\text{H}\}$ NMR (121.42 MHz, C₆D₆, 293 K): δ 4.6 (s). $^{13}\text{C}\{^1\text{H}\}$ NMR (75.42 MHz, C₆D₆, 293 K): δ 205.6 (s, C=O), 149.7 (s, *ipso*-Ph), 125.5 (s, Ph), 106.7 (s, $\equiv\text{CC}$), 80.1 (t, $J(\text{PC}) = 7.0$ Hz, OsC \equiv), 75.0 (s, Cp), 57.8 (s, CH₂), 49.4 (s, CPh₂), 31.1 (s, CH₃), 30.7 (second-order system, PCH), 21.5, 20.7 (both s, PCMe). Anal. Calcd for C₃₈H₆₂OsP₂ (%): C, 59.82; H, 7.61. Found: C, 59.50; H, 7.72.

Preparation of Os(η^5 -C₅H₅){C \equiv CC(OCH₃)Ph₂}(P^iPr_3)₂ (12). A solution of **8** (65 mg, 0.07 mmol) in 7 mL of tetrahydrofuran was treated with a solution of KOH (50 mg, 85%, 0.76 mmol) in 1 mL of methanol. After the mixture was stirred for 10 min at room temperature, the resulting yellow solution was concentrated to dryness. The residue was extracted with 7 mL of toluene, and the mixture was filtered through Kieselguhr. The solution was concentrated to dryness, and the residue was washed three times with 2 mL of cold pentane to give a yellow solid. Yield: 40 mg (70%). IR (Nujol): $\nu(\text{C}\equiv\text{C})$ 2071 cm⁻¹. ^1H NMR (300 MHz, CDCl₃, 293 K): 7.51–7.47 (m, 4 H, Ph), 7.23–7.11 (m, 6 H, Ph), 4.84 (s, 5 H, Cp), 3.25 (s, 3 H, OCH₃), 2.27 (m, 6 H, PCH), 1.15 (dvt, $J(\text{HH}) = 7.0$ Hz, $N = 11.5$ Hz, 18 H, PCMe), 1.12 (dvt, $J(\text{HH}) = 7.5$ Hz, $N = 12.3$, 18 H, PCMe). $^{31}\text{P}\{^1\text{H}\}$ NMR (121.42 MHz, C₆D₆, 293 K): δ 4.9 (s). $^{13}\text{C}\{^1\text{H}\}$ NMR (75.42 MHz, C₆D₆, 293 K): 148.6 (s, *ipso*-Ph), 128.5, 127.5, 126.3 (all s, Ph), 104.4 (s, $\equiv\text{CC}$), 85.9 (t, $J(\text{PC}) = 17.2$ Hz, OsC \equiv), 82.4 (s, CPh₂), 74.9 (s, Cp), 51.3 (s, OCH₃), 30.6 (second-order system, PCH), 21.4, 20.9 (both s, PCMe). Anal. Calcd for C₃₉H₆₀OsP₂ (%): C, 58.76; H, 7.60. Found: C, 58.27; H, 7.62. MS (FAB⁺): m/e 767 ($\text{M}^+ - \text{OCH}_3$).

X-ray Structure Determination of [OsH(η^5 -C₅H₅)(C \equiv CPh)(P^iPr_3)₂PF₆] (2) and [Os(η^5 -C₅H₅)(CCH=CPh₂)(P^iPr_3)₂](PF₆)₂ (9). A summary of the fundamental crystal and refinement data of the compounds **2** and **9** is given in Table 4. Crystals of **2** and **9** showing well-defined faces were mounted on a Bruker-Siemens Smart CCD diffractometer equipped with a normal focus, 2.4 kW sealed tube X-ray source (Molybdenum radiation, $\lambda = 0.71073$ Å) operating at 50 kV and 20 mA. Data were collected over a quadrant of the reciprocal space by a combination of two frame sets for **2** and over a hemisphere by a combination of three sets for **9**. The cell parameters were determined and refined by least-squares fits of all reflections collected. Each frame exposure time was of 20 s covering 0.3° in ω . Coverage of the unique sets were over 100% complete to at least 27° in θ . The first 50 frames were recollected at the end of the data collection to monitor crystal decay. The

Table 4. Crystal Data and Data Collection and Refinement for [OsH(η^5 -C₅H₅)(C \equiv CPh)(P^iPr_3)₂]PF₆ (2) and [Os(η^5 -C₅H₅)(CCH=CPh₂)(P^iPr_3)₂](PF₆)₂ (9)

$S^c [\text{all data}]$	1.071	0.963

^a $R1(F) = \sum ||F_o| - |F_c|| / \sum |F_o|$. ^b $wR2(F^2) = \{\sum [w(F_o^2 - F_c^2)^2] / \sum [w(F_c^2)^2]\}^{1/2}$. ^c $\text{Goof} = S = \{\sum [w(F_o^2 - F_c^2)^2] / (n - p)\}^{1/2}$, where *n* is the number of reflections, and *p* is the number of refined parameters.

absorption correction was made using SADABS.³⁹ The structure was solved by Multan and Fourier methods using SHELXS.³⁹ Full-matrix least-squares refinement was carried out using SHELXL97³⁹ minimizing $w(F_o^2 - F_c^2)^2$. Weighted *R* factors (*R*_w) and all goodness of fit *S* are based on *F*²; conventional *R* factors (*R*) are based on *F*.

Theoretical Calculations. All the ab initio calculations have been carried out using the Gaussian-98 suite of programs.³⁸ The calculations have been performed at the MP2 level using the LANL2DZ pseudopotential and basis set for the metal atoms and the 6-31G basis set for the rest of the molecule. The extended Hückel calculations were carried out using the program CACAO and its built-in basis set.³⁶

Acknowledgment. We thank the DGES (PROJECT PB-98-1591, Programa de Promoción General del Conocimiento) for financial support. M.B. thanks the DGA (Diputación General de Aragón) for a grant.

Supporting Information Available: Tables of atomic coordinates and equivalent isotropic displacement coefficients, anisotropic thermal parameters, and bond distances and angles for **2** and **9**. This material is available free of charge via the Internet at <http://pubs.acs.org>.
