Received June 5, 1984

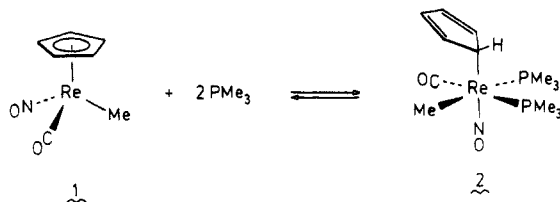

The reaction of $(\eta^5\text{-C}_9\text{H}_7)\text{Re}(\text{CO})_3$, **6**, with PMe_3 produces *fac*-($\eta^1\text{-C}_9\text{H}_7$) $\text{Re}(\text{CO})_3(\text{PMe}_3)_2$, **7**, in high yield. The rate of reaction is greatly accelerated compared to that for $(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{CO})_3$, **3**, and PMe_3 . **6** also reacts with $\text{P}(n\text{-Bu})_3$ and 2,2'-bipyridyl to give η^1 -indenyl-bis(phosphine) adduct **10** and η^1 -indenyl-bipyridyl adduct **13**, respectively. Complexes **7**, **10**, and **13** all undergo degenerate intramolecular 1,3 rhenium migrations on the NMR time scale at 25 °C. The fluxionality is frozen out at low temperature. **6** reacts with H_2O and acetone at 88 °C to give $[\text{Re}(\text{CO})_3\text{OH}]_4 \cdot 2[\text{C}_9\text{H}_7\text{C}(\text{CH}_3)_2\text{OH}]$, **14**.

Introduction

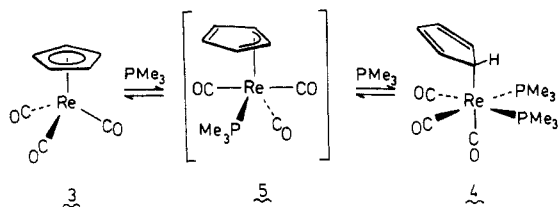

Basolo first proposed η^5 -cyclopentadienyl ring slippage to explain the rapid second-order substitution reaction of PPh_3 and $(\eta^5\text{-C}_5\text{H}_5)\text{Rh}(\text{CO})_2$.¹ In 1980, Werner reported the first example of the conversion of an $\eta^5\text{-C}_5\text{H}_5$ to an isolable $\eta^1\text{-C}_5\text{H}_5$ complex. He found that reaction of $(\eta^5\text{-C}_5\text{H}_5)\text{Pd}(\eta^1\text{-2-RC}_3\text{H}_4)\text{P}(i\text{-Pr})_3$ and $\text{P}(i\text{-Pr})_3$ produces a mixture of $(\eta^5\text{-C}_5\text{H}_5)\text{Pd}(\eta^1\text{-2-RC}_3\text{H}_4)\text{P}(i\text{-Pr})_3$ and $(\eta^1\text{-C}_5\text{H}_5)\text{Pd}(\eta^1\text{-2-RC}_3\text{H}_4)\text{P}(i\text{-Pr})_3$ (eq 1).² At about the same time we in-

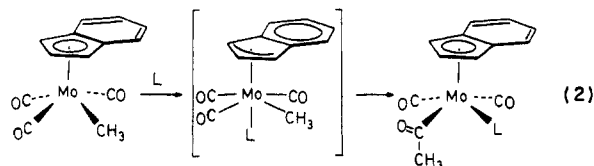

dependently found that $(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{CO})(\text{NO})(\text{CH}_3)$, **1**, reacts rapidly with PMe_3 to form the stable ring-slippage product $(\eta^1\text{-C}_5\text{H}_5)\text{Re}(\text{CO})(\text{NO})(\text{CH}_3)(\text{PMe}_3)_2$, **2**.³ Since

then, there have been a growing number of reports of $\eta^5\text{-C}_5\text{H}_5$ to $\eta^1\text{-C}_5\text{H}_5$ conversions.⁴ In a recent paper, we reported the reaction of $(\eta^5\text{-C}_5\text{H}_5)\text{Re}(\text{CO})_3$, **3**, with PMe_3 produces *fac*-($\eta^1\text{-C}_5\text{H}_5$) $\text{Re}(\text{CO})_3(\text{PMe}_3)_2$, **4**.^{4b} The rate of reaction of **3** depended on the concentration of both Re and PMe_3 ; this requires requires an intermediate mono-(phosphine) adduct. The only reasonable 18-electron structure for this intermediate is the $\eta^3\text{-C}_5\text{H}_5$ complex **5**.

We have been unable to directly observe the $\eta^3\text{-C}_5\text{H}_5$ complex **5**. Apparently, the reaction of **5** with PMe_3 to give the $\eta^1\text{-C}_5\text{H}_5$ bis(phosphine) adduct **4** is much faster than the rate of formation of **5** from PMe_3 and **3**. In an effort to directly observe an $\eta^3\text{-C}_5\text{H}_5$ metal complex, we have sought a substituted $\eta^5\text{-C}_5\text{H}_5$ compound which would show enhanced reactivity with PMe_3 but which would produce an $\eta^3\text{-C}_5\text{H}_5$ which is no more reactive toward PMe_3 than **5**. The η^5 -indenyl system is an excellent choice for such a system since in the conversion of the η^5 -indenyl to an η^3 -indenyl system, the full aromaticity of the benzene ring is achieved. More rapid substitution reactions of η^5 -indenyl systems compared with η^5 -cyclopentadienyl systems were first observed by Mawby for the reaction of $(\eta^5\text{-C}_9\text{H}_7)\text{Mo}(\text{CO})_3\text{CH}_3$ and PPh_3 which gave the phosphine-substituted acyl complex $(\eta^5\text{-C}_9\text{H}_7)\text{Mo}(\text{CO})_2(\text{PPh}_3)(\text{COCH}_3)$ (eq 2).⁵ The rate of reaction was 10 times faster than that

for the analogous $\eta^5\text{-C}_5\text{H}_5$ complex. To explain the rate acceleration and the observed second-order kinetics, an η^3 -indenyl intermediate was proposed. Subsequently, similar rapid substitution of η^5 -indenyl complexes has been seen in a number of systems.⁶ Recently Basolo reported a 10^8 rate enhancement for the second-order phosphine substitution reaction of $(\eta^5\text{-indenyl})\text{Rh}(\text{CO})_2$ compared with $(\eta^5\text{-C}_5\text{H}_5)\text{Rh}(\text{CO})_2$.^{6g-i}

Here we report our attempt to observe an η^3 intermediate in the reaction of $(\eta^5\text{-C}_9\text{H}_7)\text{Re}(\text{CO})_3$, **6**, with PMe_3 . Although we were unable to directly detect an $\eta^3\text{-C}_9\text{H}_7$ species, dramatic effects of the indenyl group on the η^5 to η^1 conversion chemistry were noted. The rate of formation of a bis(phosphine) η^1 complex was much faster for η^5 -indenyl complex **6** than for η^5 -cyclopentadienyl complex **3**. The equilibrium between η^5 and η^1 complexes lies much farther toward the η^1 complex for the indenyl system than

for the cyclopentadienyl system. The high kinetic reactivity of η^5 -indenyl complex 6 and the high thermodynamic stability of the η^1 -indenyl products has allowed us to observe $\eta^5 \rightarrow \eta^1$ conversions driven even by the bulky $\text{P}(n\text{-C}_4\text{H}_9)_3 \equiv (\text{P}^t\text{Bu}_3)$ ligand and by the less nucleophilic 2,2'-bipyridyl (bpy) ligand.⁷

Results

The reaction of excess 0.17 M PMe_3 with a slurry of ($\eta^5\text{-C}_9\text{H}_7$) $\text{Re}(\text{CO})_3$, 6, in hexane at room temperature produced η^1 -indenyl compound 7 which was isolated as a white solid in 95% yield. The facial configuration of 7 is fully

supported by spectroscopic evidence and is analogous to *fac*-($\eta^1\text{-C}_5\text{H}_5$) $\text{Re}(\text{CO})_3(\text{PMe}_3)_2$, 4, whose structure was established by X-ray crystallography.^{4b} The IR spectrum of 7 has three CO bands at 2021, 1936, and 1894 cm^{-1} which show similar intensity ratios to the 2014, 1935, and 1890 cm^{-1} bands of 4. As detailed below, rhenium undergoes a degenerate intramolecular 1,3 migration on the indenyl ligand that is fast on the NMR time scale at room temperature and slow on the NMR time scale at -65°C . In the ^1H NMR of 7 at -65°C , no fluxionality of the $\eta^1\text{-C}_9\text{H}_7$ ligand of 7 was seen. The proton on the carbon bonded directly to rhenium appears at δ 3.81 and establishes the η^1 nature of 7; the diastereotopic PMe_3 ligands of 7 gave rise to two doublets at δ 1.74 and 1.57; the six remaining nonequivalent indenyl hydrogens gave rise to three multiplets between δ 7.40 and 6.37. In agreement with the facial configuration of 7, two ^{31}P resonances are seen at δ -43.1 and -46.6 at -70°C for the two diastereotopic PMe_3 ligands; these resonances coalesce to a single broad resonance at δ -44.5 at $+27^\circ\text{C}$ where the fluxional process exchanges the environment of the phosphine ligands. The alternate meridional configuration with trans phosphines, which would have given rise to a single phosphorus resonance at all temperatures⁸ and the meridional configuration

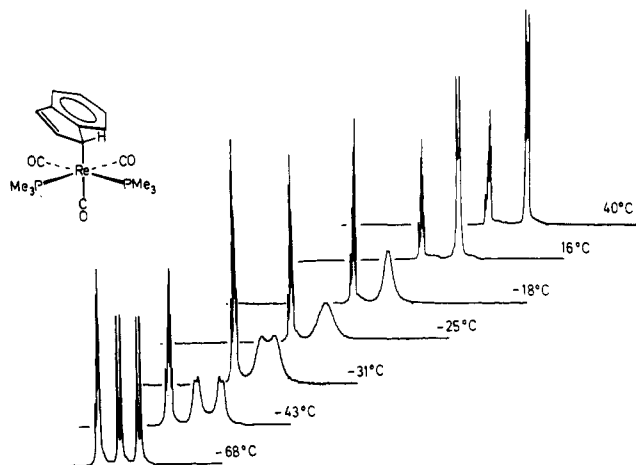

Figure 2. Variable-temperature 270-MHz ^1H NMR spectrum of 7: PMe_3 ligand resonances.

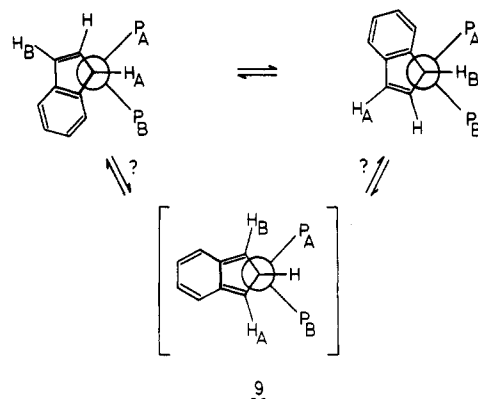

Figure 3. View down $\text{Re}-\eta^1$ -Indenyl Bond of 7. Carbonyl ligands and methyl groups on phosphorus ligands are omitted for clarity.

with *cis* phosphines, which would have given rise to two resonances at all temperatures, can be excluded on the basis of temperature-dependent ^{31}P NMR.

The fluxional process which makes all five $\eta^1\text{-C}_5\text{H}_5$ protons in 4 equivalent is rapid on the NMR time scale even at -86°C . In contrast, nonequivalence of the protons of the η^1 -indenyl ligand of 7 begins to be seen in the ^1H NMR of 7 at $+40^\circ\text{C}$. The signals for H_1 and H_3 which are sharp multiplets at δ 3.81 and 6.31 at -68°C begin to broaden at -43°C , coalesce at about 16°C , and appear as a broad singlet at 40°C (Figure 1). The ABCD pattern of H_4 , H_5 , H_6 , H_7 between δ 7.36 and 6.84 at -68°C is also temperature dependent and is converted to a sharp AA'BB' pattern at 16°C . The signals due to the diastereotopic PMe_3 ligands of 7 are also temperature dependent and are transformed from two doublets at δ 1.86 and 1.69 at -68°C to a virtually coupled triplet at δ 1.72 at 40°C (Figure 2). This virtual coupling can occur only if the temperature-dependent process does not involve PMe_3 dissociation. ΔG^\ddagger for the fluxional process was calculated to be $12.0 \pm 0.1 \text{ kcal mol}^{-1}$ by comparison of simulated and observed spectra.⁹ The barrier is substantially greater than the barrier for $\eta^1\text{-C}_5\text{H}_5$ compound 4 which is rapidly fluxional at -86°C (estimated $\Delta G^\ddagger \leq 7 \text{ kcal mol}^{-1}$). The larger barrier for η^1 -indenyl systems compared with $\eta^1\text{-C}_5\text{H}_5$ systems has been observed previously; indeed, the

(7) To our knowledge the $\eta^5\text{-C}_9\text{H}_7$ to $\eta^1\text{-C}_9\text{H}_7$ conversions reported here represent the first examples of the conversion of an $\eta^5\text{-C}_9\text{H}_7$ complex into an isolable $\eta^1\text{-C}_9\text{H}_7$ complex. In 1977 Green reported that $\text{Rh}(\text{C}_2\text{H}_4)_2(\eta^5\text{-C}_9\text{H}_7)$ reacts with excess *t*-BuNC to form $\text{Rh}(\sigma\text{-C}_9\text{H}_7)(\text{t-BuNC})_4$ for which only infrared data was reported.^{6a}

(8) This makes the reasonable assumption that rotation about the long $\text{Re}-\text{indenyl}$ bond is rapid at -60°C .

(9) The computer simulation was done by using the computer program NMRSIM (written by M. Chen); the line width at half height (-68°C) was taken to be 8.5 Hz which is the excess broadening due to phosphorus coupling as seen in the low- and high-temperature ^1H NMR.

only other transition-metal η^1 -indenyl compound is non-fluxional.¹⁰ The more rapid fluxional behavior of η^1 -C₅H₅ compound 4 can best be explained by a 1,2 migration process. A similar 1,2 migration in the indenyl compound 7 would lead to intermediate 9 in which the aromaticity of the aryl ring is lost (Figure 3). In fact, 1,2 migration in the indenyl system may be retarded to such an extent that the observed fluxionality may be due to a direct 1,3 shift.

The reaction of PMe₃ (1.29 M) with (η^5 -C₉H₇)Re(CO)₃, 6, in CD₂Cl₂ at -65 °C was followed by ¹H NMR in an effort to detect a mono(phosphine) η^3 -indenyl intermediate 8. A rapid reaction was observed in which starting material 6 disappeared and a single new product, *fac*-(η^1 -C₉H₇)Re(CO)₃(PMe₃)₂, 7, appeared. No evidence for η^3 intermediate 8 was seen; we estimate that 5–10% of intermediate 8 would have been easily detected. In the reaction of cyclopentadienyl complex 3 with PMe₃, the rate determining step was the formation of an η^3 -C₅H₅ mono-phosphine intermediate which then reacted rapidly with PMe₃ to produce the η^1 -C₅H₅ bis(phosphine) product 4. We had hoped that the generation of the fully aromatic aryl ring in the mono(phosphine) η^3 -indenyl intermediate 8 would increase our chances of observing an η^3 intermediate by accelerating the rate of the first phosphine addition step relative to the second phosphine addition step. However since no 8 was detected, apparently the second phosphine addition to 8 is still faster than the initial phosphine addition which generates 8.

The rate of reaction of PMe₃ with 6 was measured by ¹H NMR at -65 °C. The pseudo-first-order rate constant was determined to be $(4.0 \pm 0.10) \times 10^{-4} \text{ s}^{-1}$; assuming a second-order rate law as observed for 4, a second-order rate constant was calculated to be $3.3 \times 10^{-4} \text{ M}^{-1} \text{ s}^{-1}$ at -65 °C; this corresponds to $\Delta G^\ddagger = 15 \text{ kcal mol}^{-1}$ at -65 °C. For comparison, the second-order rate constant for reaction of PMe₃ with η^5 -C₅H₅ compound 4 at 88.3 °C was found to be about $1.8 \times 10^{-5} \text{ M}^{-1} \text{ s}^{-1}$ which corresponds to $\Delta G^\ddagger = 29 \text{ kcal mol}^{-1}$ at 88 °C. The difference in ΔG^\ddagger of about 14 kcal mol⁻¹ between these two reactions is comparable to the $>10^8$ rate enhancement ($\Delta\Delta G^\ddagger > 10.7 \text{ kcal mol}^{-1}$) reported by Basolo for related cyclopentadienyl- and indenylrhodium compounds.^{6a-i} These large rate differences are undoubtedly related to the generation of a fully aromatic benzene ring in the proposed η^3 -indenyl intermediate 8.

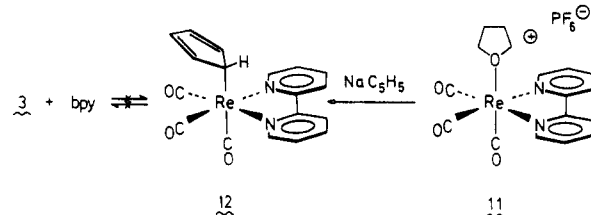

The η^1 -indenyl complex 7 is kinetically and thermodynamically a very stable system. When a solution of 7 was heated at 65 °C for 1 h in the probe of a Bruker WH-270 NMR spectrometer, no dissociation of PMe₃ was observed and no formation of substitution products was seen.

PBu₃ Adduct. Previously, we had unsuccessfully attempted to form η^1 -C₅H₅-bis(tri-*n*-butylphosphine) adducts by reaction of PBu₃ either with (η^5 -C₅H₅)Re(CO)₃, 3, or with (η^5 -C₅H₅)Re(CO)(NO)CH₃, 1, both of which form stable bis(phosphine) adducts with the less hindered PMe₃. No reaction between 3 and PBu₃ was seen up to 100 °C. When 1 was heated at 90 °C with PBu₃, a second-order reaction occurred to give (η^5 -C₅H₅)Re(NO)(PBu₃)CH₃ and (η^5 -C₅H₅)Re(NO)(PBu₃)COCH₃; the reaction was suggested to proceed via an unobserved η^3 -C₅H₅ mono(phosphine) intermediate.^{3,4}

The enhanced stability of η^1 -indenyl complex 7 encouraged us to study the reaction of PBu₃ with 6 in an effort to observe a more crowded bis(phosphine) η^1 -indenyl complex. When PBu₃ was added to a slurry of 6 in hexane,

an immediate reaction took place to produce a light yellow solution from which *fac*-(η^1 -C₉H₇)Re(CO)₃(PBu₃)₂, 10, was isolated in 87% yield. The structure of 10 was assigned on the basis of the similarity of its IR and ¹H and ³¹P NMR to those of 7. In particular, the low-temperature ¹H NMR of 10 has seven nonequivalent hydrogens, the low-temperature ³¹P NMR has two resonances for the diastereotopic PBu₃ ligands, and the IR shows a characteristic three-band pattern expected for a facial isomer. As in the case of PMe₃ adduct 7, the room-temperature ¹H and ³¹P NMR provide evidence for a fluxional η^1 -indenyl system. It is remarkable that the tendency of the indenyl system to assume an η^1 configuration is strong enough to allow two bulky PBu₃ ligands with cone angles of 132° to enter cis positions.¹¹

2,2'-Bipyridyl Adduct. To see if nitrogen ligands could induce an η^5 to η^1 rearrangement, we heated (η^5 -C₅H₅)Re(CO)₃, 3, with neat 2,2'-bipyridyl (bpy) at 80 °C but failed to observe any reaction. The fact that the desired η^1 -C₅H₅-bpy adduct is a stable isolable compound was established by independent synthesis. Reaction of the known *fac*-Re(CO)₃(bpy)Br¹² with AgPF₆ in tetrahydrofuran led to precipitation of silver bromide and formation of the cationic THF adduct 11 which was isolated and characterized. Addition of NaC₅H₅ to a THF solution of 11 led to precipitation of orange *fac*-(η^1 -C₅H₅)Re(CO)₃(bpy), 12, in 95% yield.¹³ η^1 -C₅H₅ complex 12 decomposes slowly in acetone at room temperature over several days. No (η^5 -C₅H₅)Re(CO)₃, 3, is produced upon decomposition.

With the more reactive indenyl complex 6, we observed a slow reaction at 54 °C with 1 equiv of bpy in benzene-*d*₆. The 1:1 adduct *fac*-(η^1 -C₉H₇)Re(CO)₃(bpy), 13, formed in 88% yield and was isolated as a red solid. In the low-temperature ¹H NMR of 13, the 15 chemically different protons give rise to at least 14 different multiplets between δ 4.4 and 8.7. In the room-temperature NMR, a fluxional process interconverts three pairs of protons on the indenyl ligand and four pairs of protons on the bpy ligand, and seven different multiplets are seen. As expected for the assigned facial configuration, the two halves of the bpy ligand are NMR nonequivalent at low temperature and equivalent at room temperature. A meridional configuration would have led to two nonequivalent pyridyl rings at all temperatures. While 7 and 10 have three CO stretches in the IR, 13 has only two bands, a sharp band at 2004 cm⁻¹ and a broad band at 1900 cm⁻¹.

We suggest that the failure of bpy to react with (η^5 -C₅H₅)Re(CO)₃, 3, is a kinetic problem. The ability of bpy to induce an η^5 to η^1 rearrangement is much less than that of PMe₃ or PBu₃. For example (η^5 -C₉H₇)Re(CO)₃, 6, reacts with PMe₃ rapidly at -65 °C but only reacts slowly with bpy at +54 °C. We know that independently synthesized *fac*-(η^1 -C₅H₅)Re(CO)₃(bpy), 12, decomposes slowly in solution at room temperature and that solutions of (η^5 -C₅H₅)Re(CO)₃, 3, are stable at 80 °C. Therefore, the rate

(11) Tolman, C. A. *Chem. Rev.* 1977, 77, 313–348.

(13) At 25 °C, BrRe(CO)₃(bpy) reacts slowly (approximately 1.5 days) with NaC₅H₅ in THF to give 12; however, decomposition of 12 begins to occur before reaction is complete.

of formation of *fac*-(η^1 -C₅H₅)Re(CO)₃(bpy), **12**, must be extremely slow. We have no information regarding the relative thermodynamic stability of **3** and **12** since we have never been able to observe their interconversion.

Rhenium Tetramer Formation. Since the η^5 -indenyl system underwent η^5 to η^1 rearrangement with both PMe₃ (cone angle 118°) and the bulkier PBu₃ (cone angle 132°), we attempted to look for a bis(phosphine) η^1 -indenyl product in the reaction with the extremely bulky tricyclohexylphosphine ligand (PCy₃, cone angle 170°). When a solution of (η^5 -C₉H₇)Re(CO)₃, **6**, was heated with PCy₃ in acetone-*d*₆ for 3 days at 55 °C, starting material disappeared and a new product appeared. The new material had NMR resonances for a nonfluxional indenyl system even at room temperature. No change in the PCy₃ ¹H NMR resonances was seen, and we suspected that it might not be involved in the reaction.

Indeed, when **6** was heated in acetone for 2 weeks at 88 °C, a new compound, [Re(CO)₃OH]₄·2[C₉H₇C(CH₃)₂OH], **14**, was isolated. The reaction is accelerated by added

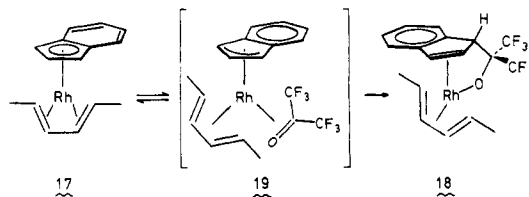

water. The structure of **14** consists of a cubic array with four Re(CO)₃ and four OH units at the vertices; in addition, two molecules of 1-[(1-hydroxy-1-methyl)ethyl]indene are associated with each rhenium tetramer. The ¹H NMR of this material had all the indenyl resonances seen in the product formed in the presence of PCy₃. In addition, the spectrum has singlets at δ 1.29 and 0.93 for the diastereotopic methyl groups α to the indenyl alcohol, at δ 6.60 for the μ_3 -OH of the rhenium tetramer, and at δ 3.91 for the hydroxy group of the indenyl alcohol; these resonances were not in the PCy₃ reaction that was run in deuterated acetone. The 2:1 nature of the adduct was established by elemental analysis and by integration of ¹H NMR hydroxyl resonances, both of which underwent slow exchange with D₂O.

The known [Re(CO)₃OH]₄, **15**,¹⁴ and the known indenyl alcohol **16**¹⁵ were synthesized as described previously. When a 1:5 molar ratio of **15** and **16** were dissolved in acetone, the same 1:2 adduct **14** was formed as shown by comparison of melting point behavior and ¹H NMR and IR spectra. In acetone-*d*₆, 1:2 adduct **14** apparently dissociates since its ¹³C and ¹H NMR spectra are the superposition of the NMR spectra of the isolated components **15** and **16**. In THF, the IR spectrum of **14** is identical with that of [Re(CO)₃OH]₄·4THF in THF; this provides further evidence for the dissociation of 1:2 adduct **14** in solution.

Green has observed a related reaction of (η^5 -indenyl)-rhodium complex **17** with hexafluoroacetone that produces the indenyl-alcoholate complex **18** shown below.¹⁶ To explain the stereochemistry of the product in which the oxygen and alkene ligands are both bonded to rhodium, Green proposed that carbon-carbon bond formation might

occur via intermediate **19** with an η^3 -indenyl ligand and a coordinated ketone. The reaction reported here may occur by a similar mechanism.

Experimental Section

General Data. Solvents were distilled from sodium and benzophenone (C₆D₆, hexane), CaH₂ (CD₂Cl₂), or B₂O₃ (acetone) prior to use. All reactions were run under dry nitrogen, except where indicated. ¹H NMR spectra were recorded on a Bruker WH-270 (270 MHz) or IBM WP200 (200 MHz) spectrometer; ¹³C NMR (50.10 MHz) and ³¹P NMR (80.76 MHz) were recorded on a JEOL FX-200 spectrometer. ³¹P chemical shifts are referenced in parts per million from 85% H₃PO₄; upfield shifts are recorded as negative. Infrared spectra were recorded on a Beckman 4230 infrared spectrometer. Mass spectra were obtained on a AEI-MS-902 mass spectrometer. Melting points were determined on a Thomas-Hoover capillary melting point apparatus and are uncorrected. Elemental analyses were performed by Schwarzkopf Microanalytical Labs.

***fac*-(η^1 -C₉H₇)Re(CO)₃(PMe₃)₂, **7**.** PMe₃ (1.03 mmol, 0.17 M) was condensed into a slurry of (η^5 -C₉H₇)Re(CO)₃, **6** (132 mg, 0.34 mmol), in 6 mL of hexane at -78 °C. The slurry was stirred for 1 h at *J*_{PH+PH} °C, concentrated to 2 mL, and filtered to give **7** (174 mg, 95%) as a white solid: mp (sealed capillary) 146–162 °C dec; ¹H NMR (acetone-*d*₆, -68 °C) δ 7.36 (m, 2 H), 6.99 (m, 1 H), 6.94 (m, 1 H), 6.84 (m, 1 H), 6.31 (d, *J* = 4.6 Hz, 1 H), 3.81 (m, 1 H), 1.86 (d, *J*_{PH} = 8.3 Hz, 9 H), 1.69 (d, *J* = 8.5 Hz, 9 H); ¹H NMR (acetone-*d*₆, 40 °C) δ 7.39 (m, 2 H), 6.99 (m, 1 H), 6.90 (m, 2 H), 5.16 (br, 2 H), 1.72 (three lines, *J*_{PH+PH} = 8.2 Hz, 18 H); ¹H NMR (CD₂Cl₂, -68 °C) δ 7.40 (m, 2 H), 6.96 (m, 3 H), 6.37 (m, 1 H), 3.81 (m, 1 H), 1.74 (d, *J* = 8.1 Hz, 9 H), 1.57 (d, *J* = 8.1 Hz, 9 H); ¹³C NMR (acetone-*d*₆, -70 °C) δ 194.1 and 193.0 (two broad resonances separated by 50 Hz assigned either as two broad singlets or two overlapping doublets due to chemically non-equivalent CO's trans to PMe₃), 190.9 (CO trans to C₉H₇), 157.5 (C8, C9), 147.5 (d, *J* = 158 Hz), 120.9 (d, *J* = 158 Hz), 119.8 (d, *J* = 158 Hz), 113.2 (d, *J* = 167 Hz), 29.7 (d, *J* = 139 Hz), 18.3 (qt, *J* = 130, 32 Hz, PMe₃); ³¹P{¹H} NMR (CD₂Cl₂, -70 °C) δ -43.1 (d, *J* = 31 Hz), -46.6 (d, *J* = 31 Hz); ³¹P{¹H} NMR (CD₂Cl₂, 0.09 M Cr(acac)₃, 27 °C) δ -44.5; IR (CH₂Cl₂) 2021 (vs), 1936 (s), 1894 (s) cm⁻¹.

Anal. Calcd for C₁₈H₂₆O₃P₂Re: C, 40.22; H, 4.69. Found: C, 40.48; H, 4.88. Exact mass calcd for ¹⁸⁷ReC₁₈H₂₆O₃P₂ 538.0836, found 538.0840.

Kinetics for Formation of **7.** PMe₃ (0.34 mmol, 1.29 M) was condensed into an NMR tube containing a -76 °C CD₂Cl₂ solution of **6** (0.029 mmol, 0.112 M) and 1,4-bis(trimethylsilyl)benzene (0.02 M) as internal standard. The tube was sealed, shaken at -76 °C, and placed in an NMR probe precooled to -65 °C. The initial ¹H NMR spectrum showed 15% reaction, and the reaction was monitored ten times over 39 min until 49% reaction had occurred. The observed pseudo-first-order rate constant for disappearance of **6** was found to be $(4.0 \pm 0.1) \times 10^{-4}$ s⁻¹. The second-order rate constant was calculated to be 3.3×10^{-4} M⁻¹ s⁻¹ using 1.22 M as the average PMe₃ concentration. This corresponds to ΔG^\ddagger = 15 kcal mol⁻¹ at -65 °C.

***fac*-(η^1 -C₉H₇)Re(CO)₃(PBu₃)₂, **10**.** A slurry of **6** (136 mg, 0.35 mmol) and PBu₃ (142 mg, 0.70 mmol) in hexane was stirred for 1 h at 25 °C. The resulting yellow solution was evaporated to give **10** (241 mg, 0.31 mmol, 87% yield) as a viscous oil contaminated by about 5% excess PBu₃. ¹H NMR (CD₂Cl₂, -70 °C) δ 7.47 (m, 2 H), 7.05 (m, 2 H), 6.93 (m, 1 H), 6.46 (m, 1 H), 4.18 (m, 1 H), 2.00 (m, 12 H), 1.43 (m, 24 H), 0.97 (m, 18 H); ¹H NMR (CD₂Cl₂, 27 °C) δ 7.29 (m, 2 H), 6.82 (m, 2 H), 6.75 (m, 1 H), 5.32 (br, 2 H), 1.76 (br), 1.27 (br), 0.78 (br) (total of 54 H); ¹³C NMR (CD₂Cl₂, -68 °C) δ 194.0 and 192.9 (two broad resonances separated by 50 Hz assigned either as two broad singlets or two

***fac*-($\eta^1\text{-C}_5\text{H}_5$) $\text{Re}(\text{CO})_3(\text{bpy})$, 12.** Addition of $\text{NaC}_5\text{H}_5\cdot\text{THF}$ (76 mg, 0.455 mmol) to a THF (25 mL) solution of 11 (300 mg, 0.455 mmol, 0.018 M) led to precipitation of orange 12 (212 mg, 0.43 mmol, 95%): mp (sealed capillary) $180\text{--}181.5^\circ\text{C}$ dec; ^1H NMR (acetone- d_6) δ 8.88 (m, 2 H), 8.57 (m, 2 H) 8.18 (m, 2 H), 7.68 (m, 2 H), 5.24 (s, 5 H); $^{13}\text{C}\{^1\text{H}\}$ NMR (acetone- d_6 , 0.09 M $\text{Cr}(\text{acac})_3$) δ 155.9, 153.6, 139.5, 127.8, 124.6, 111.2 (C_5H_5); IR (CH_2Cl_2) 2010 (vs), 1904 (s), 1890 (shoulder) cm^{-1} .

Anal. Calcd for $\text{C}_{18}\text{H}_{13}\text{N}_2\text{O}_3\text{Re}$: C, 43.99; H, 2.66; N, 5.70. Found: C, 43.83; H, 2.59; N, 5.68.

***fac*-($\eta^1\text{-C}_9\text{H}_7$) $\text{Re}(\text{CO})_3(\text{bpy})$, 13.** An NMR tube containing a solution of 6 (67.1 mg, 0.174 mmol) and 2,2'-bipyridyl (27.2 mg, 0.174 mmol) in benzene- d_6 (0.35 mL) was heated at $54.0 \pm 0.2^\circ\text{C}$ and periodically monitored by ^1H NMR. After 60 h, 6 and bpy were 95% converted to a new compound, 13, with resonances at δ 8.11 (m, 2 H), 6.82 (m, 1 H), 6.70 (m, 2 H), 6.56 (br, 4 H), 6.48 (m, 2 H), 6.14 (m, 2 H), and 5.3 (br, 2 H). When the NMR tube was opened, 13 spontaneously crystallized. Hexane was added, and red microcrystalline 13 [83 mg, 88%, mp (sealed capillary) $172\text{--}178^\circ\text{C}$ dec] was isolated by filtration. Recrystallization of 13 from THF/hexane gave 13 as an orange powder: ^1H NMR (CD_2Cl_2 , -67°C) δ 8.73 (d, $J = 5.2$ Hz, 1 H), 8.16 (d, $J = 5.0$ Hz, 1 H), 7.84 (m, 1 H), 7.75 (m, 1 H), 7.67 (m, 1 H), 7.38 (d, $J = 8.1$ Hz, 1 H), 7.22 (m, 2 H), 6.51 (m) and 6.47 (m) (2 H total), 6.67 (dd, $J = 4.5, 1.6$ Hz, 1 H), 6.26 (m, 1 H), 5.86 (d, $J = 7.5$ Hz, 1 H), 5.78 (d, $J = 4.5$ Hz, 1 H), 4.43 (d, $J = 1.6$ Hz, 1 H); ^1H NMR (CD_2Cl_2 , 30°C) δ 8.56 (d, $J = 5.3$ Hz, 2 H), 7.76 (m, 2 H), 7.66 (d, $J = 8.0$ Hz, 2 H), 7.21 (m, 24 H), 6.59 (m, 1 H), 6.46 (br, 4 H), 5.15 (br, 2 H); $^{13}\text{C}\{^1\text{H}\}$ NMR (CD_2Cl_2 , -71°C) δ 153.7,

151.6, 150.2, 147.9, 141.2, 138.9, 136.8, 136.5, 125.5, 125.2, 122.6, 120.2, 119.3, 119.0, 118.4, 118.2, 112.3, 105.3, 42.1, only one weak resonance at δ 201.5 was seen for the CO's; IR (CH_2Cl_2) 2004 (vs), 1900 (s, br) cm^{-1} .

Anal. Calcd for $\text{C}_{22}\text{H}_{15}\text{O}_3\text{N}_2\text{Re}$: C, 48.79; H, 2.79; N, 5.17. Found: C, 48.79; H, 2.87; N, 5.37.

Attempted Reaction of 6 with PCy_3 . An NMR tube containing a solution of 6 (9.5 mg, 0.025 mmol) and PCy_3 (14 mg, 0.05 mmol) in 0.35 mL of acetone- d_6 was heated at 55°C for 3 days and monitored by NMR. After 3 days, the resonances due to 6 were replaced by a new set of resonances at δ 7.73 (m, 1 H), 7.32 (m, 1 H), 7.21 (m, 1 H), 7.15 (m, 1 H), 6.71 (ddd, $J = 6, 2, 0.7$ Hz, 1 H), 6.52 (dd, $J = 6, 2$ Hz, 1 H), and 3.57 (m, 1 H). No change was observed in the resonances due to PCy_3 .

[$\text{Re}(\text{CO})_3\text{OH}$] $_4\cdot 2[\text{C}_9\text{H}_7\text{C}(\text{CH}_3)_2\text{OH}]$, 14, from 6 and Acetone. A sealed tube containing a solution of 6 (275.8 mg, 0.716 mmol, 0.26 M) and 2.8 mL of acetone was heated at 88°C for 14 days. Evaporation of volatiles and trituration of the oily residue with 1:5 CH_2Cl_2 /hexane (3 mL) led to formation of a white solid 14 (208 mg, 0.139 mmol, 77%): mp (sealed capillary) $195\text{--}197^\circ\text{C}$ dec; ^1H NMR (acetone- d_6) δ 7.73 (m, 1 H), 7.32 (m, 1 H), 7.21 (m, 1 H), 7.15 (m, 1 H), 6.84 (ddd, $J = 5.7, 2.0, 0.7$ Hz, 1 H) 6.60 (s, 2 H), 6.52 (dd, $J = 5.6, 1.9$ Hz, 1 H), 3.57 (m, 1 H), 3.91 (br, 1 H), 1.29 (s, 3 H), 0.93 (s, 3 H); $^{13}\text{C}\{^1\text{H}\}$ NMR (THF- d_8) δ 197.3, 146.2, 146.0, 137.7, 132.6, 127.0, 125.9, 125.0, 121.2, 72.4, 63.5, 29.7, 25.6; IR (THF) 3426 (br), 2027 (s), 1927 (vs) cm^{-1} .

Anal. Calcd for $\text{C}_{36}\text{H}_{32}\text{O}_{18}\text{Re}_4$: C, 28.88; H, 2.15. Found: C, 28.48; H, 2.10.

In a similar reaction run in H_2O /acetone (15:85), 6 was converted to 14 in 90% isolated yield after only 1 day.

[$\text{Re}(\text{CO})_3\text{OH}$] $_4\cdot 2[\text{C}_9\text{H}_7\text{C}(\text{CH}_3)_2\text{OH}]$, 14, from [$\text{Re}(\text{CO})_3\text{OH}$] $_4$, 15, and $\text{C}_9\text{H}_7\text{C}(\text{CH}_3)_2\text{OH}$, 16. A solution of [$\text{Re}(\text{CO})_3\text{OH}$] $_4$, 15,¹³ (204 mg, 0.18 mmol, 0.045 M) and $\text{C}_9\text{H}_7\text{C}(\text{CH}_3)_2\text{OH}$ ¹⁴ (154 mg, 0.88 mmol, 0.22 M) in 4 mL of acetone was stirred at 25°C for 30 min. Workup as above gave 14 (190 mg, 0.126 mmol, 70% yield) which was identified by IR, NMR, and melting point.
