 $[Pd(C_6H_4NO_2-p)I(PPh_3)_2] \ and \ [Pd(Ph)CI(Ph_2PCH_2PPh_2)] \ do \ not \ react \ with \ NO \ but \ react \ with \ NO_2 \ to \ give \ [Pd(NO_3)_2(OPPh_3)(PPh_3)] \ and \ [PdCI(NO_3)(Ph_2PCH_2CH_2PPh_2)] \ respectively. The structure \ of \ [Pd(NO_3)_2(OPPh_3)(PPh_3)] \ has been \ confirmed \ by \ X-ray \ crystallography, the metal \ co-ordination \ polyhedron being \ planar \ with \ trans \ monodentate \ nitrate \ groups. Reaction \ of \ [Pt(R)I(PPh_3)_2] \ (R = C_6H_4NO_2-p \ or \ Ph) \ with \ NO_2 \ gave \ [Pt(R)(NO_3)(PPh_3)_2], \ species \ shown \ spectroscopically \ to \ contain \ monodentate \ nitrate. \ Treatment \ of \ [Pd(NO_2)_2(PPh_3)_2] \ with \ NO_2 \ gave \ [Pd(NO_3)_2(PPh_3)_2], \ while \ NO \ or \ CO \ caused \ deoxygenation \ of \ [Pd(NO_3)_2(PPh_3)_2] \ (L = PPh_3 \ or \ PEt_3) \ and \ [Pt(Ph)(NO_3)_2(PPh_3)_2]. \ Reaction \ of \ [Ni(NO_3)_2(PPt_3)_2] \ with \ NO \ or \ NO_2 \ afforded \ [Ni(NO_3)_2(OPEt_3)_2]. \ The \ possible \ mechanisms \ of \ these \ oxygen-transfer \ reactions \ are \ briefly \ discussed.$ 

A number of  $d^0$ ,  $d^8$ , and  $d^{10}$  alkyl¹ and aryl² complexes react with NO giving compounds containing the N-alkyl- or N-aryl-N-nitrosohydroxylaminato ligand, [ONN(R)O]<sup>-</sup>. In contrast, however, it has been reported<sup>3,4</sup> that Pt<sup>II</sup> alkyls afford only nitro or nitrato derivatives. Thus cis-[PtMe<sub>2</sub>L<sub>2</sub>] (L = PMe<sub>2</sub>Ph³ or PEt<sub>3</sub><sup>4</sup>) reacted with NO giving, initially, cis,cis,cis-[PtMe<sub>2</sub>-(NO<sub>2</sub>)<sub>2</sub>L<sub>2</sub>] which subsequently isomerised and reacted with [PtMe<sub>2</sub>L<sub>2</sub>] to give trans-[PtMe(NO<sub>2</sub>)L<sub>2</sub>] and fac-[PtMe<sub>3</sub>-(NO<sub>2</sub>)L<sub>2</sub>] (L = PMe<sub>2</sub>Ph). cis-[PtMe<sub>2</sub>(PMe<sub>2</sub>Ph)<sub>2</sub>] also reacted with NO<sub>2</sub> giving analogous nitrato complexes and, under different conditions, mixtures of [PtMe(NO<sub>2</sub>)(PMe<sub>2</sub>Ph)<sub>2</sub>] and [PtMe(NO<sub>3</sub>)(PMe<sub>2</sub>Ph)<sub>2</sub>] could be formed.<sup>3</sup>

In seeking to extend the scope of reactions of metal-aryl complexes with oxides of nitrogen, particularly NO, with the hope of observing 'insertion' processes, we have studied the behaviour of trans-[M(R)X(PPh<sub>3</sub>)<sub>2</sub>] (M = Pd or Pt, R = Ph or  $C_6H_4NO_2$ -p, X = Cl or I) with NO and NO<sub>2</sub>.

# **Experimental**

The starting materials  $[Pt(R)I(PPh_3)_2]$  (R = Ph or  $C_6H_4$ - $NO_2$ -p),  $^5$   $[Pd(Ph)Cl(PPh_3)_2]$ ,  $^6$   $[Pd(C_6H_4NO_2$ - $p)I(PPh_3)_2]$ ,  $^7$   $[Pd(Ph)Cl(Ph_2PCH_2CH_2PPh_2)]$ , and  $[Ni(NO_3)_2(PEt_3)_2]^8$  were prepared as described in the literature. The complexes  $[Pd(NO_x)_2(PR_3)_2]$  (x=2 or 3, R=Ph or Et) were obtained by reaction of  $[PdCl_2(PR_3)_2]$  with  $NaNO_2$  or  $AgNO_3$  in chloroform. NO gas was prepared as described elsewhere and purified by passage through KOH pellets and a trap containing molecular sieves cooled at -78 °C.  $NO_2-N_2O_4$  was prepared by the reaction of NO gas with oxygen or by heating lead nitrate,  $^{10}$  and was trapped at -78 °C. The trap containing white  $N_2O_4$  was degassed thoroughly with dry  $N_2$  to remove oxygen. All solvents were thoroughly dried and degassed prior to use, and all reactions were carried out under dry  $N_2$  or in the presence of NO or  $NO_2$  with  $N_2$  as a diluant.

I.r. spectra were recorded using a PE297 spectrophotometer

and <sup>1</sup>H n.m.r. spectra obtained using Varian HA100 or JEOL JMN-PMX-60 instruments. <sup>31</sup>P N.m.r. spectra were obtained using a JEOL FX90 instrument at the University of Sheffield. Analyses were performed by the Microanalytical Laboratories of the Chemistry Department, University of Birmingham.

Reaction of  $[Pd(C_6H_4NO_2-p)I(PPh_3)_2]$  with  $NO_2$ :  $[Pd(NO_3)_2(OPPh_3)(PPh_3)]$ .— $NO_2$  was bubbled into a solution of  $[Pd(C_6H_4NO_2-p)I(PPh_3)_2]$  (0.5 g, 0.57 mmol) in dichloromethane (30 cm<sup>3</sup>) for 10 min. The mixture was then flushed with  $N_2$  and filtered, the filtrate being evaporated in vacuo. The residue was crystallised twice from dichloromethane and n-hexane (the filtrate from the first crystallisation being pale purple). The complex was isolated as orange-yellow microcrystals (yield 0.31 g, 70%).

Reaction of [Pd(Ph)Cl(Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>)] with NO<sub>2</sub>: cis-[PdCl(NO<sub>3</sub>)(Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>)].—NO<sub>2</sub> was bubbled through a solution of cis-[Pd(Ph)Cl(Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>)] (0.5 g, 0.71 mmol) in dichloromethane (30 cm<sup>3</sup>) for 10 min. The solution was purged with N<sub>2</sub> and evaporated in vacuo. The resulting orange oil was crystallised from dichloromethane and n-hexane, and the complex obtained as pale yellow crystals which were filtered off and dried in vacuo (yield 0.3 g, 70%).

trans-[Pt( $C_6H_4NO_2$ -p)( $NO_3$ )(PPh<sub>3</sub>)<sub>2</sub>].—Method 1. To [Pt( $C_6H_4NO_2$ -p)I(PPh<sub>3</sub>)<sub>2</sub>] (0.25 g, 0.26 mmol) dissolved in chloroform (50 cm<sup>3</sup>), AgNO<sub>3</sub> (0.09 g, 0.53 mmol) was added and the mixture stirred at room temperature (r.t.) for 2 d. The resulting suspension was filtered and the filtrate treated with n-hexane. The volume of the solution was partially reduced in vacuo giving a white solid which was filtered off. This compound was recrystallised from dichloromethane and n-hexane, affording the complex as white needles which were filtered off and dried in vacuo (yield 0.19 g, 78%). The complex was isolated with 0.5 mol of dichloromethane of crystallisation [ $^1H$  n.m.r. (CDCl<sub>3</sub>):  $\delta$ , 7.7—7.1 (m, 30 H, PPh<sub>3</sub>), 7.1—6.6 (A<sub>2</sub>B<sub>2</sub> pair, 4 H, C<sub>6</sub>H<sub>4</sub>NO<sub>2</sub>), and 5.28 (s, 1 H, CH<sub>2</sub>Cl<sub>2</sub>)].

Method 2.  $NO_2$  was passed through a solution of  $[Pt(C_6H_4NO_2-p)I(PPh_3)_2]$  (0.25 g, 0.26 mmol) in dichloromethane (30 cm<sup>3</sup>) for 10 min. The mixture was then purged with  $N_2$  and evaporated in vacuo, giving a pink-white solid. This was crystallised from dichloromethane—n-hexane mixtures to which

<sup>+</sup> Bis(nitrato-O)(triphenylphosphine)(triphenylphosphine oxide)-palladium(11).

Supplementary data available (No. SUP 56573, 7 pp.): H-atom coordinates, thermal parameters, least-squares planes data. See Instructions for Authors, J. Chem. Soc., Dalton Trans., 1986, Issue 1, pp. xvii—xx. Structure factors are available from the editorial office.

a small amount of decolourising charcoal was added. The *complex* was obtained, after filtration and drying *in vacuo*, as white needles (yield 0.15 g, 61%). The reaction could also be carried out in benzene, and the complex was isolated containing 1 mol of benzene of crystallisation.

trans-[Pt(Ph)(NO<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>].—To [Pt(Ph)I(PPh<sub>3</sub>)<sub>2</sub>] (1 g, 1.08 mmol) dissolved in chloroform (30 cm<sup>3</sup>), AgNO<sub>2</sub> (0.21 g, 1.4 mmol) was added and the mixture stirred overnight at room temperature. The resulting suspension was filtered and the filtrate evaporated in vacuo to give a white solid. This compound was recrystallised from dichloromethane and n-hexane, affording the complex as white microcrystals which were filtered off and dried in vacuo (yield 0.85 g, 93%).

[Pt(Ph)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>].—Method 1. The complex was prepared in the same way as its  $C_6H_4NO_2$ -p analogue by Method 2 above, using [Pt(Ph)I(PPh<sub>3</sub>)<sub>2</sub>] (0.25 g, 0.27 mmol). The resulting red-brown solution was purged with N<sub>2</sub>, evaporated in vacuo, and the residue crystallised from dichloromethane—ethern-hexane mixtures to which decolourising charcoal had been added. The complex was filtered off, dried in vacuo, and obtained as white microcrystals (yield 0.15 g, 65%).

Method 2. The complex was obtained as in Method 1 for the  $C_6H_4NO_2$ -p analogue above, using [Pt(Ph)I(PPh<sub>3</sub>)<sub>2</sub>] (0.4 g 0.43 mmol) and AgNO<sub>3</sub> (0.12 g, 0.71 mmol) in chloroform (30 cm<sup>3</sup>) overnight. The complex was recrystallised as in Method 1 above, and was isolated as white microcrystals (yield 0.28 g, 76%).

Method 3.  $NO_2$  was passed through a solution of [Pt-(Ph)( $NO_2$ )(PPh<sub>3</sub>)<sub>2</sub>] (0.25 g, 0.3 mmol) in dichloromethane (30 cm<sup>3</sup>) for 5—10 min. The resulting solution was purged with  $N_2$ , evaporated in vacuo, and the residue crystallised as in Method 1. The complex was obtained as white microcrystals (yield 0.18 g, 71%).

Reaction of [Pd(NO<sub>2</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] with NO<sub>2</sub>: [Pd(NO<sub>3</sub>)<sub>2</sub>-(PPh<sub>3</sub>)<sub>2</sub>].—NO<sub>2</sub> was passed through a solution of [Pd-(NO<sub>2</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] (0.25 g, 0.35 mmol) in dichloromethane (30 cm<sup>3</sup>) for 10—15 min. The solution was then purged with N<sub>2</sub> and evaporated in vacuo leaving a yellow solid which was recrystallised from dichloromethane–n-hexane mixtures. The complex was filtered off and dried in vacuo, being isolated as a yellow powder (yield 0.24 g, 90%).

Reaction of [Pd(NO<sub>3</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] with NO: [Pd(NO<sub>2</sub>)<sub>2</sub>-(PPh<sub>3</sub>)<sub>2</sub>].—NO was passed through a dichloromethane solution (30 cm<sup>3</sup>) of [Pd(NO<sub>3</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] (0.5 g, 0.66 mmol) for 20—25 min. The solution was then purged with N<sub>2</sub> and filtered giving a pale yellow solid and an orange-yellow filtrate. The solid was recrystallised from dichloromethane—n-hexane mixtures, and dried in vacuo, giving [Pd(NO<sub>2</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] as pale yellow microcrystals (yield 0.17 g, 35%). Evaporation of the filtrate gave an orange-yellow solid which was also recrystallised from dichloromethane—n-hexane mixtures, but was shown by i.r. spectroscopy to be a mixture of [Pd(NO<sub>2</sub>)<sub>2</sub>-(PPh<sub>3</sub>)<sub>2</sub>] and [Pd(NO<sub>3</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] or a mixed nitro—nitrato species. Separation of the components of this mixture could not be achieved by chromatography on alumina using CH<sub>2</sub>Cl<sub>2</sub> as alumnt

Reaction of  $[Pd(NO_3)_2(PEt_3)_2]$  with NO:  $[Pd(NO_2)_2(PEt_3)_2]$ .—NO was passed through a dichloromethane solution  $(30\,cm^3)$  containing  $[Pd(NO_3)_2(PEt_3)_2]$  (0.5 g, 1.0 mmol) for 30 min. The solvent was then evaporated in vacuo and the residue chromatographed on silica gel using ethyl acetate as eluant. The pale yellow fraction was collected, evaporated in vacuo and the

solid recrystallised from dichloromethane–n-hexane mixtures. The *complex* was obtained as a white powder (yield 0.19 g, 41%).

Reaction of [Pt(Ph)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>] with NO.—NO was passed through a solution of [Pt(Ph)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>] (0.25 g) in dichloromethane (30 cm<sup>3</sup>) for 30 min. The solution was then purged with N<sub>2</sub> and evaporated in vacuo. The product, which was not purified, was identified by i.r. spectroscopy as a mixture of the starting material and [Pt(Ph)(NO<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>].

Reaction of [Pd(NO<sub>3</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] with CO: [Pd(NO<sub>2</sub>)<sub>2</sub>-(PPh<sub>3</sub>)<sub>2</sub>].—CO was passed through a dichloromethane solution (30 cm<sup>3</sup>) of [Pd(NO<sub>3</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] (0.75 g) for 1 h at r.t. The solution was then purged with N<sub>2</sub> and filtered to give a pale yellow solid. The [Pd(NO<sub>2</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] so formed was recrystallised from dichloromethane—n-hexane mixtures and dried in vacuo. Further product was obtained from the filtrate by its evaporation in vacuo, and chromatographing the residue on silica gel using ethyl acetate—n-hexane mixtures (70:30 v/v) as eluant. The yellow fraction afforded, on reducing the solution in vacuo, the complex as yellow crystals (combined yield 0.35 g, 49%).

Reaction of [Pd(NO<sub>3</sub>)<sub>2</sub>(PEt<sub>3</sub>)<sub>2</sub>] with CO: [Pd(NO<sub>2</sub>)<sub>2</sub>-(PEt<sub>3</sub>)<sub>2</sub>].—The complex was obtained in the same way as its PPh<sub>3</sub> analogue, using [Pd(NO<sub>3</sub>)<sub>2</sub>(PEt<sub>3</sub>)<sub>2</sub>] (0.5 g, 1.0 mmol) and was isolated as a white powder (yield 0.26 g, 55%).

Reaction of [Ni(NO<sub>3</sub>)<sub>2</sub>(PEt<sub>3</sub>)<sub>2</sub>] with NO: [Ni(NO<sub>3</sub>)<sub>2</sub>-(OPEt<sub>3</sub>)<sub>2</sub>].—NO was passed through a solution of [Ni(NO<sub>3</sub>)<sub>2</sub>-(PEt<sub>3</sub>)<sub>2</sub>] (0.5 g, 1.19 mmol) in benzene (30 cm<sup>3</sup>) for 25 min. During this time the colour of the solution changed from deep green to yellow. On purging the solution with N<sub>2</sub> and adding light petroleum (b.p. 40—60 °C), a yellow solid was precipitated. This was filtered off and recrystallised from benzene-light petroleum giving the *complex* as yellow prisms (yield 0.25 g, 46%).

Reaction of [Ni(NO<sub>3</sub>)<sub>2</sub>(PEt<sub>3</sub>)<sub>2</sub>] with NO<sub>2</sub>: [Ni(NO<sub>3</sub>)<sub>2</sub>-(OPEt<sub>3</sub>)<sub>2</sub>].—The reaction described above was repeated using NO<sub>2</sub> in place of NO. The complex was isolated as described above (yield 0.31 g, 57%).

cis-[Pd(Ph)(NO<sub>2</sub>)(Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>)]·CH<sub>2</sub>Cl<sub>2</sub>.— [Pd(Ph)Cl(Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>)]·CH<sub>2</sub>Cl<sub>2</sub> (0.5 g, 0.71 mmol) and AgNO<sub>2</sub> (0.14 g, 0.91 mmol) were stirred together in chloroform (30 cm<sup>3</sup>) for 24 h. The mixture was filtered and the filtrate evaporated in vacuo. The residue was crystallised from dichloromethane (n-hexane mixtures for the presence of charcoal), affording the complex as pale yellow crystals which were filtered off and dried in vacuo (yield 0.43 g, 85%).

Crystal and Molecular Structure Analysis of [Pd(NO<sub>3</sub>)<sub>2</sub>-(OPPh<sub>3</sub>)(PPh<sub>3</sub>)].—C<sub>36</sub>H<sub>30</sub>N<sub>2</sub>O<sub>7</sub>P<sub>2</sub>Pd, M = 770.99 (crystallises from dichloromethane and n-hexane as irregular, yellow bricks; crystal dimensions  $0.39 \times 0.23 \times 0.24$  mm), orthorhombic, a = 14.442(6), b = 25.618(14), c = 18.639(19) Å, U = 6.896(8) Å<sup>3</sup>,  $D_m = 1.47$ ,  $D_c = 1.485$  g cm<sup>-3</sup>, Z = 8, space group Pbca ( $D_2^{1.5}$ , no. 61), Mo- $K_\alpha$  radiation ( $\bar{\lambda} = 0.710.69$  Å),  $\mu$ (Mo- $K_\alpha$ ) = 6.70 cm<sup>-1</sup>, F(000) = 3.136.

Three-dimensional X-ray diffraction data were collected in the range  $3.5 < 20 < 50^{\circ}$  on a Nicolet/Syntex R3 diffractometer by the  $\omega$ -scan method. 2 608 Independent reflections for which  $I/\sigma(I) > 3.0$  were corrected for Lorentz and polarisation effects. The structure was solved by standard Patterson and Fourier methods and refined by block-diagonal least squares. Hydrogen atoms were placed in calculated positions (C-H 0.98 Å); their contributions were included in structure factor

calculations ( $B = 7.0 \text{ Å}^2$ ) but no refinement of positional parameters was permitted. Refinement converged at R 0.0541 with allowance for anisotropic thermal motion of all non-nydrogen atoms and for the anomalous scattering of palladium and phosphorus. Table 1 lists the atomic positional parameters with estimated standard deviations. Scattering factors were taken from ref. 11; unit weights were used throughout the refinement; computer programs formed part of the Sheffield X-ray system.

## **Results and Discussion**

(i) Reactions with NO.—There was no reaction between pure NO and [M(R)I(PPh<sub>3</sub>)<sub>2</sub>] (M = Pd or Pt, R = Ph or C<sub>6</sub>H<sub>4</sub>NO<sub>2</sub>-p) or [Pd(Ph)Cl(Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>)] in either dichloromethane or benzene under ambient conditions. Various reaction times were used but even after several hours no new products were identified. This is in marked contrast to the work described by Puddephatt and Thompson<sup>3</sup> and Wilkinson and co-workers<sup>4</sup> who were able to obtain, from Pt<sup>II</sup> methyls under mild conditions, dinitroplatinum(IV) derivatives.

The reason for this apparent lack of reactivity is not obvious. It could be related to steric factors, since the previous work had used complexes of PMe<sub>2</sub>Ph and PEt<sub>3</sub>, but this seems unlikely in view of the ability of [M(R)X(PPh<sub>3</sub>)<sub>2</sub>] to react with CO via an associative process to give metal–acyl derivatives.<sup>5</sup> It is possible that the metal–aryl–triphenylphosphine complexes are less 'electron rich' than [PtMe<sub>2</sub>L<sub>2</sub>] (L = PMe<sub>2</sub>Ph or PEt<sub>3</sub>), and this could contribute to reduced reactivity. It is perhaps less surprising that Pd does not react to give Pd<sup>IV</sup> dinitro derivatives, since Pd<sup>IV</sup> complexes are significantly less stable than their Pt<sup>IV</sup> analogues. Indeed, there are very few stable Pd<sup>IV</sup> complexes containing Pd–C  $\sigma$  bonds, and these involve the electronegative  $C_6F_5^-$  group.<sup>12</sup>

(ii) Reactions with NO<sub>2</sub>.—In studying the reactions of [M(R)X(PPh<sub>3</sub>)<sub>2</sub>] with NO, it was observed that low yields of new products were formed when small amounts of NO<sub>2</sub> were present in the NO gas [see section (iii)]. Ultimately, it was established that the yield of these products could be significantly increased by carrying out the reaction with NO<sub>2</sub> alone.

Reaction of  $[Pd(C_6H_4NO_2-p)I(PPh_3)_2]$  with  $NO_2$  in dichloromethane afforded orange-yellow crystalline  $[Pd(NO_3)_2-(OPPh_3)(PPh_3)]$ . After removal of the solid, the filtrate was pale purple, suggesting that  $I_2$  might have been formed in the reaction. The complex was characterised by elemental analysis (Table 2), i.r. (Table 3), and  $^{31}P$  n.m.r. spectroscopy (Table 4), and by an X-ray crystallographic examination.

The i.r. spectra of the product established that the  $C_6H_4$ - $NO_2$ -p ligand was absent, there being no absorptions in the range 1 560—1 575 cm<sup>-1</sup> (out-of-plane C-H bending modes) or at 1 500s, 1 340s, 850m, and 825m cm<sup>-1</sup>, characteristic of the p- $NO_2$  group. However, new absorptions were present in the regions 1 515s—1 475s, 1 285s—1 260s, 1 020m—965m, and

Figure. Molecular structure of [Pd(NO<sub>3</sub>)<sub>2</sub>(OPPh<sub>3</sub>)(PPh<sub>3</sub>)] with atom labelling

(PPh<sub>3</sub>)], was unambiguously established by a single-crystal X-ray study. The structure of the molecule is illustrated in the Figure with the atom labelling used in corresponding Tables. Selected bond lengths and angles (together with estimated standard deviations) are given in Table 5.

The molecule comprises square-planar co-ordinated palladium(II) with two mutually trans O-bonded, unidentate nitrate ligands; the remaining sites are occupied by triphenylphosphine and triphenylphosphine oxide ligands; the bond angle at the oxygen atom of this latter ligand is 132.1°. The pattern of nitrogen-oxygen bond lengths clearly reflects the donor or terminal natures of the oxygen atoms. The nitrate groups are each closely planar, with small in-plane angular deviations from perfect trigonality; the ligands are orientated in such a way that one of the formally terminal oxygen atoms of each group lies rather close to the palladium (2.89 and 2.85 Å), one above and one below the mean co-ordination plane, but, necessarily, well displaced from the axial sites. The angles at the donor oxygen atoms of these nitrate ligands are rather small and the palladium is displaced (0.19 and 0.29 Å) from the nitrate planes. The phenyl rings are each planar and other geometric features of the ligands are unexceptional. There are two close contacts between the palladium atom and hydrogen atoms on phenyl rings; an intramolecular contact (2.74 Å) to H(36) on the ortho carbon atom of a phenyl ring of the triphenylphosphine ligand, this contact being on the same side of the co-ordination plane as that to O(7). The other contact is intermolecular and more distant (3.00 Å) to H(29)(-x, -y, -z) on a meta carbon atom of a different phenyl ring of the same ligand; this contact being on the same side of the co-ordination plane as O(4). These contacts may be simply regarded as the occupancy of sites in the van der Waals envelope of the complex, but such contacts have long been recognised15 as of importance in the catalysis of homogeneous hydrogenation.

The reaction of cis-[Pd(Ph)Cl(Ph<sub>2</sub>PCH<sub>2</sub>CH<sub>2</sub>PPh<sub>2</sub>)] with NO<sub>2</sub> in dichloromethane similarly resulted in cleavage of the Pd-C bond and formation of cis-[PdCl(NO<sub>3</sub>)(Ph<sub>2</sub>PCH<sub>2</sub>-CH<sub>2</sub>PPh<sub>2</sub>)]. The i.r. spectrum of this complex showed that the phenyl group was absent but that monodentate NO<sub>3</sub><sup>-</sup> had been formed

Reaction of trans-[Pt(R)I(PPh<sub>3</sub>)<sub>2</sub>] (R = Ph or  $C_6H_4NO_2$ -p) with NO<sub>2</sub> afforded the nitrato species [Pt(R)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>] without cleavage of the Pt-C bond. These complexes could be prepared alternatively by metathetical displacement of I<sup>-</sup> by NO<sub>3</sub><sup>-</sup> using AgNO<sub>3</sub> in chloroform. The i.r. spectra of the nitrato species were consistent with the presence of the aryl ligands and with monodentate NO<sub>3</sub><sup>-</sup>. The <sup>31</sup>P n.m.r. spectra of [Pt(Ph)I(PPh<sub>3</sub>)<sub>2</sub>] and [Pt(Ph)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>] each revealed triplets [ $^1J_1^{195}$ Pt-P) ca. 3 000 Hz], consistent with two equivalent P nuclei in trans configurations.

Thus there is a significant difference between the reactions of related  $d^8$  Pd and Pt aryl complexes with NO<sub>2</sub>. The cleavage of Pd-C bonds is not exceptional, since they are generally more reactive than Pt-C bonds, and are known to be readily cleaved by oxidising agents, notably halogens. <sup>16</sup> NO<sub>2</sub> is a fairly strong oxidising agent being comparable, in aqueous solution at least, to bromine

In the reactions described above, NO<sub>2</sub> was always present in excess, conditions generally comparable to the generation of [PtMe<sub>2</sub>(NO<sub>3</sub>)<sub>2</sub>(PMe<sub>2</sub>Ph)<sub>2</sub>] from [PtMe<sub>2</sub>(PMe<sub>2</sub>Ph)<sub>2</sub>].<sup>3</sup> If insufficient NO<sub>2</sub> was used in the work described here, then a mixture of nitro and nitrato complexes was formed, as indicated by i.r. spectral studies.

The formation of nitrato products in these reactions could occur via an intramolecular oxygen-transfer process involving a cyclic intermediate incorporating co-ordinated nitro and nitrito groups, as depicted in Scheme 1, or via a direct O transfer from 'free' NO<sub>2</sub> to a co-ordinated NO<sub>2</sub> or ONO ligand. The

intramolecular process is analogous to that proposed for the conversion of  $[Pt(NO)(NO_3)(PPh_3)_2]$  into  $[Pt(NO_2)_2-(PPh_3)_2]^{17}$  That  $NO_2$  can act as a source of O atoms for the oxygenation of co-ordinated nitrite was demonstrated by the treatment of  $[Pd(NO_2)_2(PPh_3)_2]$  and  $[Pt(Ph)(NO_2)(PPh_3)_2]$  with  $NO_2$ , when  $[Pd(NO_3)_2(PPh_3)_2]$  and  $[Pt(Ph)(NO_3)-(PPh_3)_2]$  were formed. The nature of these complexes was established by elemental analyses and i.r. spectral measurements (which clearly established the presence of  $NO_3^-$  and absence of  $NO_2^-$ ) and, indirectly, by  $^{31}P$  n.m.r. spectroscopy. The  $^{31}P$  n.m.r. spectrum of authentic  $[Pd(NO_3)_2(PPh_3)_2]$  was compared with that of the bis-nitrate made as described above, and shown to be identical. It was noted that  $\delta(P)$  and  $^1J(PtP)$  for  $[Pt(Ph)(NO_3)(PPh_3)_2]$  were significantly different to those of its nitro analogue.

Possible mechanisms for the formation of  $[Pd(NO_3)_2-(OPPh_3)(PPh_3)]$  from  $[Pd(C_6H_4NO_2-p)I(PPh_3)_2]$  might involve initial addition of  $NO_2$  giving  $[Pd(C_6H_4NO_2-p)I-(NO_2)_2(PPh_3)_2]$ , analogous to  $[PtMe_2(NO_2)_2L_2]$  (L =  $PMe_2Ph$  or  $PEt_3$ ). A Reductive elimination of  $p-IC_6H_4NO_2$  would then give  $[Pd(NO_2)_2(PPh_3)_2]$  which could be further oxygenated by  $NO_2$ , as shown, to give  $[Pd(NO_3)_2(PPh_3)_2]$ . Such a mechanism does not account for the formation of  $Ph_3PO$ , however. The phosphine oxide could arise *via* dissociation of  $PPh_3$  from an intermediate, oxidation of the free ligand by  $NO_2$ , and recombination to give co-ordinated  $Ph_3PO$ . The oxygenation could also occur in an intramolecular process, *via* a co-ordinated  $P^V$  intermediate, as shown in Scheme 2. Such a process is similar to that involving deoxygenation of

$$\begin{array}{c} \downarrow \\ \downarrow \\ M - N \end{array} \longrightarrow \begin{array}{c} \downarrow \\ M - N \end{array} \longrightarrow \begin{array}{c} \downarrow \\ M + NO \end{array}$$

Scheme 2.

 $\rm [Ni(NO_2)_2(PEt_3)_2]$  by CO, giving  $\rm [Ni(NO)(NO_2)(PEt_3)_2]$  and CO2.  $^{18}$ 

The formation of [Pt(R)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>] might also be expected to proceed *via* the intermediate [Pt(R)I(NO<sub>2</sub>)<sub>2</sub>-(PPh<sub>3</sub>)<sub>2</sub>]. However, convincing pathways for the degradation of this species to the observed product are difficult to envisage. Scheme 3 would parallel that of the reaction between

$$[Pt(R)I(PPh_3)_2] + excess NO_2 \longrightarrow [Pt(R)I(NO_2)_2(PPh_3)_2]$$

$$[Pt(R)I_2(NO_2)(PPh_3)_2] + [Pt(R)(NO_2)(PPh_3)_2]$$

$$[Pt(R)I_2(NO_2)(PPh_3)_2] + [Pt(R)(NO_2)(PPh_3)_2]$$

$$[Pt(R)I_2(NO_3)(PPh_3)_2]$$
Scheme 3.

[PtMe<sub>2</sub>(NO<sub>2</sub>)<sub>2</sub>(PMe<sub>2</sub>Ph)<sub>2</sub>] and [PtMe<sub>2</sub>(PMe<sub>2</sub>Ph)<sub>2</sub>], which gave [PtMe(NO<sub>2</sub>)(PMe<sub>2</sub>Ph)<sub>2</sub>] and [PtMe<sub>3</sub>(NO<sub>2</sub>)(PMe<sub>2</sub>-Ph)<sub>2</sub>].<sup>3</sup> It is conceivable that [Pt(R)I<sub>2</sub>(NO<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>] could

2060

undergo specific reductive elimination of I2, analogous to the loss of ethane from [PtMe<sub>3</sub>(NO<sub>2</sub>)(PMe<sub>2</sub>Ph)<sub>2</sub>] and, of course, the nitro species so formed would be readily oxygenated by NO<sub>2</sub> to the isolated nitrato products as demonstrated by us.

In an attempt to probe the viability of [Pt(R)I<sub>2</sub>(NO<sub>2</sub>)-(PPh<sub>3</sub>)<sub>2</sub>] as an intermediate, we treated [Pt(Ph)(NO<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>] with I2 in benzene at room temperature. We were unable fully to characterise the product isolated, but i.r. spectral data indicated that the phenyl group had been lost (absence of absorptions at 1 565 cm<sup>-1</sup>) and that NO<sub>2</sub> was still present, suggesting that  $[PtI_x(NO_2)(PPh_3)_2]$  (x = 1 or 3) had been formed. This suggests that if  $[Pt(R)I_2(NO_2)(PPh_3)_2]$  is an intermediate then it would be more likely reductively to eliminate RI than I<sub>2</sub>. However, the reactions were carried out under different conditions of solvent and reagents.\*

A second mechanism, Scheme 4, could involve the intermediacy of  $[Pt(R)I(NO)(NO_3)(PPh_3)_2]$ . This nitrosyl nitrate could arise by an intramolecular O-transfer reaction, viz.  $Pt(NO_2)_2 \longrightarrow Pt(NO)(NO_3)$ , although this is the reverse of that involving conversion of [Pt(NO)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>] into  $[Pt(NO_2)_2(PPh_3)_2].^{17}$ 

Scheme 4.

Alternatively, the putative nitrosyl nitrate could arise by addition of N<sub>2</sub>O<sub>4</sub> as NO<sup>+</sup>NO<sub>3</sub><sup>-</sup> or ONONO<sub>2</sub>, as implied in the formation of [Pt(NO)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>] from reaction of [Pt(C<sub>2</sub>H<sub>4</sub>)(PPh<sub>3</sub>)<sub>2</sub>] with N<sub>2</sub>O<sub>4</sub>. In an effort to examine the stability of nitrosyl aryl complexes, we treated [Pt(Ph)I-(PPh<sub>3</sub>)<sub>2</sub>] with NOCl and NO+PF<sub>6</sub>. With nitrosyl chloride, assuming that an intermediate adduct could be formed, we expected [Pt(Ph)Cl(PPh<sub>3</sub>)<sub>2</sub>] to be the ultimate product, but we could observe no reaction after 10—15 min in dichloromethane at room temperature, nor could we detect any new product after work-up of the reaction mixture. Reaction did occur between [Pt(Ph)I(PPh<sub>3</sub>)<sub>2</sub>] and NO<sup>+</sup>PF<sub>6</sub><sup>-</sup> in acetonitrile but we were unable fully to characterise the product. I.r. studies revealed coordinated MeCN [v(CN) 2 300 cm<sup>-1</sup>] and the presence of  $PF_6^-$  [v(PF) 875 cm<sup>-1</sup>], as well as the absence of NO. 'Oxidation' of organometallic species by NO<sup>+</sup>PF<sub>6</sub><sup>-</sup> in acetonitrile, with incorporation of MeCN but not NO<sup>+</sup>, has been described previously.20

Finally, it is possible that radical substitution pathways are involved, in which I is displaced by NO<sub>2</sub> giving [Pt(R)-(NO<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>] directly.

(iii) Oxygen-transfer Reactions of Palladium and Nickel Complexes.—As mentioned in sections (i) and (ii), there was no reaction between [Pd(C<sub>6</sub>H<sub>4</sub>NO<sub>2</sub>-p)I(PPh<sub>3</sub>)<sub>2</sub>] and NO, but new products were observed when NO, was present in the NO gas stream. In a reinvestigation of this reaction, following our successful identification of [Pd(NO<sub>3</sub>)<sub>2</sub>(OPPh<sub>3</sub>)(PPh<sub>3</sub>)] as the product of the reaction of the aryl iodo complex with pure NO<sub>2</sub>, we obtained a yellow solid from dichloromethane saturated

with an NO-NO<sub>2</sub> mixture. An i.r. spectral examination showed that this solid was a mixture of nitro and nitrato species, that some oxidation of PPh<sub>3</sub> to Ph<sub>3</sub>PO had occurred, and that the C<sub>6</sub>H<sub>4</sub>NO<sub>2</sub>-p group had been lost. A <sup>31</sup>P n.m.r. spectrum of the mixture in CDCl<sub>3</sub> showed three resonances, at δ 40.0, 21.6, and 18.4 p.p.m. (w.r.t. external H<sub>3</sub>PO<sub>4</sub>). The signals at 40.0 and 18.4 p.p.m. are very close to those observed for authentic [Pd(NO<sub>3</sub>)<sub>2</sub>(OPPh<sub>3</sub>)(PPh<sub>3</sub>)] (8 41.2 and 18.9 p.p.m.) and this indicates that this, or some very similar species, is present in the mixture. The other signal, at 21.6 p.p.m., could not be assigned, but may be due to  $[Pd(NO_2)_x(NO_3)_{2-x}(OPPh_3)_y(PPh_3)_{2-y}]$ . It would seem that, in this reaction, there is insufficient NO2 to cause full oxygenation of the intermediate nitro species to the final nitrato complexes.

It is conceivable that NO, either present in a reagent gas mixture, or generated as a by-product of reaction, could function as a deoxygenating agent in a manner similar to CO, viz.  $[Ni(NO_2)_2L_2X] + CO \longrightarrow [Ni(NO)L_2X] + CO_2$  (L = tertiary phosphine, X = halide).<sup>21</sup> Thus, treatment of [Pd- $(NO_3)_2L_2$ ] (L = PPh<sub>3</sub> or PEt<sub>3</sub>) and [Pd(Ph)(NO<sub>3</sub>)(PPh<sub>3</sub>)<sub>2</sub>] with NO in dichloromethane afforded, after ca. 30 min, a mixture of species including [Pd(NO<sub>2</sub>)<sub>2</sub>L<sub>2</sub>] and [Pd(Ph)-(NO<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>] (characterised by i.r. spectroscopy). This demonstrates that NO can indeed abstract O atoms from coordinated nitrate, presumably being itself converted to NO<sub>2</sub>. This is the reverse of the reaction depicted in Scheme 1.

Reaction of  $[Pd(NO_3)_2L_2]$  (L = PPh<sub>3</sub> or PEt<sub>3</sub>) with CO in dichloromethane under ambient conditions afforded reasonably good yields of [Pd(NO<sub>2</sub>)<sub>2</sub>L<sub>2</sub>] but although we expected that [Pd(NO<sub>2</sub>)<sub>2</sub>L<sub>2</sub>] would undergo further reactions with CO giving nitrosyl complexes and, possibly, isocyanato derivatives, as described in the reactions of [Pt(NO<sub>3</sub>)<sub>2</sub>(PEt<sub>3</sub>)<sub>2</sub>], <sup>17</sup> this was not observed. Further deoxygenation of NO<sub>2</sub> by CO may require more vigorous conditions than we employed.

These reactions contrast with those of [Ni(NO<sub>3</sub>)<sub>2</sub>(PEt<sub>3</sub>)<sub>2</sub>] which was reported18 to react with NO in benzene after 10 min forming  $[Ni(NO_3)_2(OPEt_3)_2]$ . This reaction does indeed occur, although we found it took 25-30 min to effect complete conversion. The differing reactivity may be related to a structural difference between [Ni(NO<sub>3</sub>)<sub>2</sub>L<sub>2</sub>] (tetrahedral) and  $[M(NO_3)_2L_2]$  (M = Pd or Pt; planar). However,  $[Ni(NO_3)_2-$ (PEt<sub>3</sub>)<sub>2</sub>] reacted instantly with NO<sub>2</sub> in benzene giving  $[Ni(NO_3)_2(OPEt_3)_2]$ , whereas treatment with  $O_2$  gave only partial conversion to the phosphine oxide complex after 7—8 h.

When [Pd(NO<sub>3</sub>)<sub>2</sub>(PPh<sub>3</sub>)<sub>2</sub>] was refluxed in dry toluene for 2-3 h, an orange-yellow solid could be obtained. I.r. spectral examinations of this material showed it to contain nitro groups (1 330 and 822 cm<sup>-1</sup>) and some co-ordinated Ph<sub>3</sub>PO (1 135 cm<sup>-1</sup>). The product was difficult to purify and reproducible microanalytical data could not be obtained. The 31P n.m.r. spectrum of the complex showed a sharp singlet at  $\delta$  23.0 p.p.m. in CDCl<sub>3</sub> (w.r.t. external H<sub>3</sub>PO<sub>4</sub>), and a number of peaks of very low intensity, presumably due to minor products or impurities. This major peak does not correspond to that in  $[Pd(NO_2)_2(PPh_3)_2]$  or  $[Pd(NO_3)_2(OPPh_3)(PPh_3)_2]$  but may be due to  $[Pd(NO_2)_x(NO_3)_{2-x}(OPPh_3)_v(PPh_3)_{2-v}]$  where x =1 or 2, i.e. a species related to but different from that obtained as one of the products of the reaction of NO + NO2 with  $[Pd(C_6H_4NO_2-p)I(PPh_3)_2].$ 

### **Conclusions**

While it is clear that NO does not react with  $[M(R)X(PPh_3)_2]$  $(M = Pd \text{ or } Pt, R = Ph \text{ or } C_6H_4NO_2-p, X = I \text{ or } Cl) \text{ under}$ ambient conditions, NO2 does, but giving differing products depending on M. The different reaction pathways may be related to the stability of the presumed intermediate [M(R)- $X(NO_2)_2(PPh_3)_2$ ]. We have shown that co-ordinated  $NO_2$  in

<sup>\*</sup> Reaction of [Pt(Ph)(NO<sub>2</sub>)(PPh<sub>3</sub>)<sub>2</sub>] with I<sub>2</sub> in dichloromethane at r.t. gave uncharacterisable products.

some planar Pd and Pt complexes can be oxygenated by NO<sub>2</sub> to co-ordinated NO<sub>3</sub>, and that O-transfer to PPh<sub>3</sub>, giving coordinated OPPh<sub>3</sub>, can also occur at Pd. Conversely, we have found that, like CO, NO can deoxygenate co-ordinated NO<sub>3</sub> to NO<sub>2</sub>. There may therefore be a subtle equilibrium in the reaction system:  $M(NO_2) + NO_2 \rightleftharpoons M(NO_3) + NO$ . It is also conceivable that certain reactions of NO with lowoxidation state species which give nitro and/or nitrito species<sup>1</sup> may in fact be reactions involving NO<sub>2</sub> present in the NO reagent gas. An example of this behaviour could be the formation of  $[\{Co(NO)_2(NO_2)\}_n]$  and  $[Co_4(NO)_8(NO_2)_3]$  $(N_2O_2)$ ] from  $[Co_2(CO)_8]$  or  $[Co(NO)(CO)_3]$  and  $NO.^{22}$ 

#### Acknowledgements

We are grateful to Johnson Matthey Co. for the loan of palladium and platinum salts, and to the S.E.R.C. for a studentship (to A. S. R.) and for funds to purchase the diffractometer. We thank Mr. T. Green for technical assistance and Dr. B. F. Taylor for recording the <sup>31</sup>P n.m.r. spectra.
