Preparation and Study of Some Dithiolylium Salts

By Ledi Menabue and Gian Carlo Pellacani,* Istituto di Chimica Generale e Inorganica, University of Modena, 41100 Modena, Italy

The salts 3,5-diamino- or 3,5-di(methylamino)-1,2-dithiolylium perchlorate or bromide and 4-chloro-(or 4bromo-)3,5-diamino- or 3,5-di(methylamino)-1,2-dithiolylium chloride or bromide have been prepared by oxidation of dithiomalonamide or NN'-dimethyldithiomalonamide. Conductivity, molecular-weight, ¹H n.m.r., u.v., i.r., and polarographic measurements are reported. The removal of a proton from the CH₂ group of the dithiomalonamides gives a five-membered ring with pseudo-aromatic character. All the experimental data support considerable π bonding between the sulphur atoms, and this confers great stability on the disulphide group. The stability of the 3,5-diamino- or 3,5-di(methylamino)-1,2-dithiolylium salts is greater than that of the 4-chloro-3,5diamino- or 3,5-di(methylamino)-1,2-dithiolylium salts. The reduction of these salts occurs in one two-electron wave. Mono- and bis-dithiolylium salts of tetrachloro-ferrate(II), -cobaltate(II), -niccolate(II), and -cuprate(II) have also been prepared. Their magnetic moments and electronic and i.r. spectra suggest a tetrahedral configuration for the $[FeCl_4]^-$ anions and a distorted tetrahedral configuration for the $[MCl_4]^{2-}$ (M = Co, Ni, or Cu) anions, and absence of co-ordination of the dithiolylium ions which act as cations.

THE co-ordination properties of dithiomalonamides, (I), have been previously studied. Dithiomalonamides are structurally analogous to \beta-dithioketones, with the

advantage of being isolable ligands which can be compared with their complexes. Previously, we have

demonstrated that in neutral media dithiomalonamide, (Ia), NN'-dimethyldithiomalonamide, (Ib), and NN'diphenyldithiomalonamide, (Ic), give SS'-co-ordinated complexes $[ML_2]$ $[M = Ni^{1,2}]$ and $Pd^{3,4}$; L = (IIa), (IIb), or (IIc)] and $[AuL_2X]$ [L = (IIa) or (IIc), X = Cl; L = (IIb), $X = [AuCl_4]^{-5}$], and in acid media NS-coordinated cationic complexes of the types [ML2]X2 $(M = Ni^{1,2} \text{ and } Pd^{3,4})$ and $[NiL_3]X_2,^{1,2}$ and neutral complexes of the type $[PdLX_2]^{3,4}[L = (Ia), (Ib), or (Ic)].$

In this work we examine the capacity of these ligands to form cations through oxidation. The cations are unsaturated five-membered cyclic disulphides and pseudoaromatic systems, (III), the stability of which may be attributed to resonance stabilization involving structures (A) and (B). The major interest in compounds of this class has been in the dye industry.6 Their use as cationic dyes and intermediates for synthetic fibres has been studied by a number of investigators.7-9 Quiniou and his co-workers 10,11 have prepared and studied a great number of 1,2-dithiolylium derivatives. Of the compounds reported in this work, only 3,5-diamino-1,2dithiolylium perchlorate has been previously studied, by Jensen et al. 12 who also prepared 3,5-diamino-1,2-dithiolylium chloride, the radioprotective properties of which have been recently investigated.¹³

EXPERIMENTAL

The ligands were prepared as previously described.1,2 The following concentrations were used: MeCO₂H, glacial; HClO₄, 70%; HCl 37%; HBr, 58%; and H₂O₂, 35%. All reagents were of pure chemical grade.

(0.625 mmol) was dissolved in a mixture of water (15 cm³), perchloric acid (5 cm³), and hydrogen peroxide (2 cm³). The warm solution was cooled and pale yellow crystals precipitated.

3,5-Diamino-4-chloro-1,2-dithiolylium chloride, [(IIIb)]Cl. On cooling a warm solution containing (Ia) (0.625 mmol) in HCl (15 cm³) and H₂O₂ (1.5 cm³), pale yellow crystals were obtained. The compound was recrystallized from ethanol and diethyl ether.

3,5-Diamino-4-bromo-1,2-dithiolylium bromide, [(IIIc)]Br. Hydrogen peroxide (2 cm³) was added dropwise to a filtered warm solution containing (Ia) (0.625 mmol) in water (40 cm³) and HBr (8 cm³). Yellow crystals were obtained on cooling.

3,5-Di(methylamino)-1,2-dithiolylium perchlorate or bromide, [(IIId)][ClO₄] or [(IIId)]Br. Iron(III) perchlorate hexahydrate or iron(III) bromide hexahydrate (0.7 mmol) in water (5 cm³) was added to a warm solution containing (Ib)(0.625 mmol) in water (40 cm³). The white crystalline compound was obtained on cooling.

4-Chloro-3,5-di(methylamino)-1,2-dithiolylium ([IIIe)]Cl. Pale yellow crystals separated after some hours from a mixture of (Ib) (12.5 mmol) in HCl (30 cm³) and H_2O_2 (4 cm³).

4-Bromo-3,5-di(methylamino)-1,2-dithiolylium bromide. ([IIIf)]Br. Hydrogen peroxide (2 cm³) was added dropwise to a filtered warm solution containing (Ib) (0.625 mmol) in water (40 cm³) and HBr (8 cm³). A yellow compound was obtained instantaneously.

All the compounds, except [(IIIb)]Cl, were recrystallized

Preparation of Metal Salts.—3,5-Diamino-1,2-dithiolylium and 4-chloro-3,5-di(methylamino)-1,2-dithiolylium tetrachloroferrate(III), [(IIIa)][FeCl₄] and [(IIIe)][FeCl₄]. Iron(III) chloride hexahydrate (6 mmol) and (Ia) [or (Ib)] (3 mmol) were dissolved in HCl (5 cm³), water (2 cm³), and H₂O₂ (2 cm³). The solution was shaken vigorously and warmed until a clear solution was obtained. Red crystalline salts separated out on cooling.

Bis(3,5-diamino-1,2-dithiolylium) tetrachlorocobaltate(II), [(IIIa)]₂[CoCl₄]. Cobalt(II) chloride hexahydrate (15 mmol) was added to a warm solution containing (Ia) (7.5 mmol) in $HCl (15 cm^3), H_2O_2 (1.5 cm^3), and water (2.5 cm^3).$ Bluegreen crystals were obtained on cooling to 0 °C.

tetrachlorocuprate(II), Bis(3,5-diamino-1,2-dithiolylium)[(IIIa)]₂[CuCl₄]. A warm solution of (Ia) (1.5 mmol) in MeCO₂H(42 cm³) and HCl (3 cm³) was added to a warm solution of Cu[O₂CMe]₂·H₂O (4.5 mmol) in MeCO₂H (22 cm³) and HCl (6 cm³). Red crystals were obtained on cooling the green solution at 0 °C for 1 h.

[Bis(4-chloro-3,5-di(methylamino)-1,2-dithiolylium] tetrachlorocobaltate(II), [(IIIe)]2[CoCl4]. A solution of CoCl2. 6H₂O (7 mmol) in HCl (10 cm³) was added to a warm solution of (Ib) (3.5 mmol) in HCl (15 cm³), water (2 cm³), and H₂O₂ (1.5 cm³). Blue-green crystals were obtained on cooling the solution at 0 °C for some hours.

 $Bis[extbf{4-}chloro-3,5-di(methylamino)-1,2-dithiolylium]$ tetrachloroniccolate(II), [(IIIe)]₂[NiCl₄]. A mixture of NiCl₂. 6H₂O (4 mmol) and (IIIe) (2 mmol) was dissolved in methylcellusolve (mcs) (15-20 cm³) and concentrated until the mcs was completely evaporated. Acetic acid (50 cm³) was rapidly added to the green crystals thus obtained. The

insoluble salt was filtered off and washed with MeCO2H and diethyl ether.

Bis[4-chloro-3,5-di(methylamino)-1,2-dithiolylium]chlorocuprate(II), [(IIIe)]₂[CuCl₄]. A solution of (Ib) (3.5 mmol) in HCl (10 cm³), water (2 cm³), and H_2O_2 (2 cm³) was added to a solution of Cu[O2CMe]2·H2O (7 mmol) in MeCo₂H (50 cm³) and HCl (5 cm³). Red crystals were obtained from the olive-green solution on cooling and shaking at 0 °C.

None of the salts could be recrystallized.

All the compounds were analyzed by conventional methods. Physical measurements were made as previously described. Deuteriated compounds were prepared by repeated exchange with D2O until the N-H stretching frequencies had largely disappeared from the infrared spectra.

¹H N.m.r. spectra were obtained with a Jeolco model C-60 HL spectrometer for solutions in deuterioacetone and D₂O. using SiMe₄ and dds, respectively, as internal standards. Polarographic curves were recorded with an AMEL multipurpose model 563-551/SU polarograph at different temperatures. A standard calomel electrode (s.c.e.) was used as reference, and the potential values were corrected for the junction potential. Aqueous solutions were used with 0.1 mol dm⁻³ [NEt₄][ClO₄] as supporting electrolyte. Molecular weights were determined with a Mechrolab Inc. vapourpressure osmometer or by the cryoscopic method.

RESULTS AND DISCUSSION

Dithiolylium Salts.—By reaction of dithiomalonamide, (Ia), and NN'-dimethyldithiomalonamide, (Ib), in HX (X = Cl or Br) and hydrogen peroxide we obtained compounds of the types (IIIb) and (IIIe) and (IIIc) and (IIIf), while by reaction in aqueous solution with FeBr₃·6H₂O or Fe[ClO₄]₃·6H₂O we obtained compounds of the types (IIIa) and (IIId). Table 1 lists the compounds and their analyses, molar conductivities, molecular weights, and melting points.

In compounds (IIIa) and (IIId) the halide ion was directly titrated by the Volhard method (X_{free} in Table 1), while in the other compounds (III) only one halide atom was directly titrated (X_{free} in Table 1); the determination of the second halide atom was obtained only after decomposition of the compounds, suggesting that the second halide atom is strongly bonded in the dithiolylium cation. The molar conductivities and the molecular weights of both sets of compounds in water suggest that they are 1:1 electrolytes.14 In our compounds the disulphide group is perfectly planar,15-17 indicating an absorption in the electronic spectrum at ca. 330 nm.18 The actual absorption was at 290-310 nm (Table 2). This behaviour is explained, as in the case of the thiuret cation, ¹⁸ if the two ϕ_{π} electron pairs on the sulphur atoms form part of a conjugated system with the remainder of the ring. The stability of the disulphide group in compounds (IIIa) and IIId) may be greater than that in other compounds (III) as suggested by the absorption at shorter wavelengths found for the former compounds.

The ¹H n.m.r. results (Table 2) are strictly consistent with the structure formulated for (III). The pseudo-

aromatic character of the dithiolylium salts is confirmed by the great downfield shift of the proton of C⁴ which appears in the ranges of olefinic and of aromatic protons ¹⁹ in (IIIa) and (IIId), with respect to the CH₂ protons of the free ligands (I). The absence of a CH proton resonance in the spectra of the remaining compounds therefore suggest a formation reaction of the type:

(Ia)
$$\leftarrow$$
 (IIIa) + H⁺ + 2e⁻

Plots of the limiting current against the drop time and concentration show that the reduction wave is diffusion-controlled for cations (IIIa), (IIIb), and (IIIc), while for

(III) indicates that the hydrogen atom on C⁴ has been substituted by a halide atom.

No polarographic reduction of the free ligands (I) was observed in water solution in the range 0 to -1.7 V. The reduction of the dithiolylium salts (III) occurs with one reversible two-electron wave (Table 2) [the total number of electrons added (n=2) being calculated from the Ilkovic equation 20] as shown by potentiometric titrations with Na₂[S₂O₈] and confirmed by comparison with the reduction current of a 10^{-3} mol dm⁻³ solution of Cd²⁺ under the same experimental conditions. We

(IIId), (IIIe), and (IIIf) the adsorption of the reduction products on the electrode alters the overall process which is diffusion-controlled only for low drop times (the $E_{\frac{1}{2}}$ values in Table 2 are recorded under such experimental conditions). The greater stability of the disulphide group in compounds (IIIa) and (IIId) is confirmed by the more negative $E_{\frac{1}{2}}$ values.

The i.r. assignments given for (Ia) by Jensen and Nielsen,²¹ the normal-co-ordinate analysis of the 3,5-dimethyl-1,2-dithiolylium cation,¹⁷ the proposed assignments for the thiuret cation,¹⁸ and the comparison with the spectra of previously studied complexes ¹⁻⁵ are taken

removal of a proton from the C^4H_2 group, which gives a pseudo-aromatic character to the five-membered ring.

The results of the spectroscopic studies indicate that the disulphide group, participating in the conjugated π -electron ring system, confers a great stability on these compounds, which may be attributed to resonance stabilization involving structures (A) and (B).

Metal Salts.—We prepared salts of the types [(IIIa)]_n-

* For details see Notices to Authors No. 7, J.C.S. Dalton, 1975, Index issue (items less than 10 pp. are supplied as full-size copies).

dithiolylium cations. The magnetic moments of all the salts are 'normal' for tetrahedral compounds,²² and those of the tetrachloroferrate (III) salts are consistent with the presence of Fe^{III} .²² The spectroscopic studies (Table 4) of our $[\text{FeCl}_4]^-$ salts were limited to poorly resolved room-temperature solid spectra, only one broad band being found at ca. 700 nm which may be assigned to a d-d transition. The electronic spectra of all the

1976 459

solid salts (Table 4) exhibited d-d bands typical of tetrachlorometallate anions having a distorted tetrahedral symmetry. 23,24

The i.r. and far-i.r. spectra of the salts closely resemble those of compounds (IIIa) and (IIId), except for some bands assignable to metal-chlorine vibrations (Table 5) in the far-i.r. region. This suggests that the nitrogen and sulphur atoms of the cations are not co-ordinated in any way to the metal atoms. The vibrational data (Table 5)

of the [FeCl₄] ions are in accord with a tetrahedral symmetry,25 and those of the other [MCl₄]2-ions agree with a distorted tetrahedral symmetry. 26-29

We thank Professor Giorgio Peyronel for stimulating discussions and for his kind support, the Istituto di Chimica Fisica of the University of Modena for the polarographic and potentiometric instruments, and Consiglio Nazionale delle Ricerche of Italy for support.
